Dear Colleague,

We are delighted to welcome you to the 26th International EUROMA conference in Helsinki, Finland, 17-19 June 2019. The conference is hosted by Aalto University School of Business, Hanken School of Economics and the HUMLOG Institute, at the premises of the Hanken School of Economics.

The theme of the 26th EurOMA Conference is:

*Operations Adding Value to Society*

This theme extends previous themes beyond manufacturing and services to wider societal and community implications and impact. The conference theme highlights a move beyond goods manufacturing to considerations of shared economy, circular economy, and to critical infrastructure and supply chains. EurOMA has had a tradition of tracks in various industries, and this theme specifically welcomes health care operations, humanitarian operations, and public sector management. But of course all traditional topics of the conference are well represented as well in 2019.

The conference program includes a total of 20 parallel sessions divided into the 41 EurOMA themes. Over 580 abstracts were submitted, of which 548 abstracts were accepted, and which resulted in the 409 final papers you see in the schedule. A total of 555 researchers from 44 countries will attend this annual conference. Notwithstanding Brexit, the largest number of participants come from the UK (120), with runner-ups being Sweden (46), Germany (42), Finland (38), Italy (27), and Brazil (23).

The EUROMA 2019 conference is preceded by three workshops on Sat and/or Sun 15-16 June 2019, as has been the case in many previous conferences: the EurOMA Doctoral Seminar, the EurOMA Publishing Workshop, and the EurOMA Young Scholars’ Workshop. New to the conference is a developmental paper workshop, young scholars’ tutoring and get-together, and many other activities that make this community so unique. The plenary speakers will be Professor Janet Godsell (Warwick Manufacturing Group), Rector, Professor Karen Spens (Hanken School of Economics), and Kalle Löövi, the Director of International Operations of the Finnish Red Cross.

The social program includes a Reception at Helsinki City Hall, Conference dinner at Finlandia Hall, and Industry visit to Finnair Cargo, where we get to enjoy a presentation of their new world-class cargo handling premises. On the way to Finnair Cargo facilities, we will spend the morning at the Finnish Science Park, Heureka, where we will also enjoy our lunch.

We thank all the researchers and authors who are contributing to the success of EurOMA 2019 Conference. Our special thanks go to the scientific committee and to the over 1400 reviewers for their invaluable and timely contribution – we are still proud of the reviews being sent out before the actual deadline, but that would not have been possible without everyone prioritising this conference in their schedules.

As always, the sponsors are a cornerstone of a successful conference. We wish to thank Paulo Foundation; the Foundation for Economic Education; Marcus Wallenberg Economic Research Foundation and the Federation of Finnish Learned Societies for their generous support.
Similarly, we thank all other sponsors and exhibitors for their financial support as well as their other contributions to the success of EurOMA 2019.

Welcome to Helsinki!

On behalf of the Organizing Committee,

Gyöngyi Kovács and Markku Kuula
Conference Co-Chairs

Analyzing Retailer-led Green Supply Chain Considering Fairness Concerns

Abhishek Sharma (aabhisheksharma01@gmail.com)

Abstract

In this study, we investigate the impact of fairness concern of a manufacturer towards the product’s greening policies and the pricing decisions in a retailer-led green supply chain, where the customer’s demand is sensitive to product’s greening level. We show that the manufacturer’s sensitivity towards fairness will negatively influence the manufacturer’s effort for product’s greening, the retailer’s market price, and the retailer’s profit. Furthermore, we find that a fairness-concerned manufacturer will put positive effort for greening when the product’s marginal production cost is lesser than that of its corresponding minimum value in the fairness-neutral channel.

Keywords: Green supply chain, Game Theory, Fairness

Introduction

Green supply chain (GSC) management has recently gained attention among academicians and practitioners of supply chain management. GSC strategies involve working with suppliers and customers, analyzing internal operations and processes, reconsidering inventory decisions, reverse logistics designs, new product development, and mitigating conflicts in channel coordination to minimize the negative impact of supply chains on the environment (Corbett and Klassen, 2006; Östlin et al., 2008; Swami and Shah, 2013; Li et al., 2016; Xu et al., 2017). Many big firms, such as Wal-Mart, Dell, Patagonia invest heavily on GSC initiatives, carbon disclosure projects, carbon footprint reduction and use these strategies to attract green conscious customers and improve their global brand image (Plambeck, 2007; Plambeck and Denend, 2011; Ghosh and Shah, 2012). Apparently, when the big retailers such as Wal-Mart influence their upstream manufacturers to take initiatives for improving the product’s greening level, the manufacturer’s may feel unfairly treated by the retailer when there is unfavorable distribution of total profit, with retailer taking more of it (Fehr and Schmidt, 1999; Loch and Wu, 2008; Sharma and Nandi, 2018; Sharma, 2019). In view of this, there is very limited literature that studies the impact of manufacturer’s fairness concerns in a green supply chain with retailer’s domination. Hence, the purpose of this study is to fill this gap in the literature by studying the impact of manufacturer’s fairness concerns on the product’s greening policies and the pricing decisions in a green supply chain with retailer’s dominance. We consider a retailer-led dyadic supply chain model, composed of
one manufacturer and one retailer, where the manufacturer invests on product’s greening and sells the product to the green-sensitive customers through the retailer. We then investigate the influence of manufacturer’s fairness concerns on the greening and pricing policies of the channel members.

The rest of the paper is organized as follows. The next section briefly describes recent related studies on supply chain with environmental factors under channel member’s fairness concerns. It is then followed by the model description of retailer-led green supply chain and then the model with manufacturer’s fairness concerns. Next, we discuss the influence of fairness concerns on different greening and pricing decisions. Finally, we conclude our work with several managerial implications and scope for future studies.

**Related Literature**

Swami and Shah (2013) investigate channel coordination in GSC environment in which both the manufacturer and the retailer put efforts for greening their operations. The authors find that ratio of the optimal greening efforts put in by the two parties is equal to the ratio of their green sensitivity ratios and greening cost ratios. Ghosh and Shah (2012) analyze the pricing and greening strategies, when the greening initiatives are undertaken individually or cooperatively by the players. The authors find that though the cooperation between the players lead to higher greening, however it also leads to higher market price. Ghosh and Shah (2015) establish cost sharing contractual mechanisms under manufacture’s greening initiatives. Song and Gao (2018) further investigate similar settings under revenue sharing contract and find that revenue sharing contract can improve the greening level of product, and increase the total profit of manufacturer and supply chain. It is recent that the researchers have started focusing on the fairness concerns of the decision makers into the conventional supply chain models. To the best of our knowledge, Cui et al. (2007) studied in the first place the fairness concerns in channel coordination. They describe fairness concern as *distributional fairness*, where a fair-minded player would experience disutility when there is an inequitable distribution of total profit compared to the other players in the supply chain. The authors show that the manufacturer can coordinate the channel and achieve maximum channel utility with a simple wholesale price contract, under retailer’s fairness concerns. Caliskan-Demirag et al. (2010) reconfirm these results by using non-linear demand function. Precisely, there are several recent studies that study the influence of fairness concerns of the channel members on the environmental supply chains. Ma et al. (2017) study closed-loop supply chains under fairness concerns and derive the optimal solutions of marketing effort, collection rate and pricing strategies for the supply chain members. Zhou et al. (2016) investigate low carbon supply chain under cooperative advertising contract and carbon emission reduction cost sharing contract based on retailer’s fairness concern. Du et al. (2017) examine both manufacturer’s and retailer’s fairness concern in the supply chain where sustainable green technology innovation efforts are put by both the channel members. Li et al. (2018) investigate pricing and carbon emission reduction decisions under revenue sharing contract by considering only the retailer’s fairness concern. In almost all the above studies, the manufacturer is assumed at the dominant position, and it is the retailer’s fairness concerns which are majorly investigated. However, the extant literature is deficient in determining the manufacturer’s fairness concerns in a green supply chain when the retailer is at dominance. To fill this gap, we propose a retailer-led green supply chain and investigate the impact of manufacturer’s fairness concerns on the greening and pricing policies.
Model without fairness concerns

We consider a two-echelon supply chain model with one manufacturer (M) and one retailer (R), where the manufacturer puts the effort for enhancing the greening level of products and sells it to the customers through a retailer. We adopt the retailer-led (R-led) Stackelberg game theory approach, where the dominant retailer’s pricing decision is based on the follower manufacturer’s greening choice. Here, the retailer decides about the market price \( p \) and the manufacturer decides about the product’s greening level \( g \). Similar to Swami and Shah (2013) and Ghosh and Shah (2015), we take market demand as a linear deterministic function of market price \( p \) and product’s greening level \( g \), i.e. market demand, \( D(p, g) = a - bp + ag \), where \( a \) is market potential \( (a > bp) \), \( b \) is customer’s price-elasticity coefficient, and \( a \) is customer’s green-sensitivity coefficient. Here, we assume that the cost of improving the product’s greening level is given by a convex function \( C(g) = \beta g^2 \), where \( \beta \) is a positive scaling parameter. Let \( w \) and \( c \) are the manufacturer’s per unit wholesale price and the product’s marginal production cost, respectively, where \( w > c \), to ensure positive profit margin for the manufacturer. Based on the above problem description, the profit function for the manufacturer (M), the retailer (R) and the whole supply chain (C) are given by:

\[
\pi_M = (w - c)D - \beta g^2 \\
\pi_R = (p - w)D \\
\pi_C = \pi_M + \pi_R = (p - c)D - \beta g^2
\]

We first set up a centralized channel model, that can be furnished as a benchmark model in which both M and R act as a single unit (or central planner) and decide the market price and product’s greening level to maximize the overall profit of supply chain. Thus, the centralized decision problem to maximize the total supply chain profit \( \pi_C \) is as follows.

\[
\max_{p, g} \pi_C = (p - c)(a - bp + ag) - \beta g^2 \tag{1}
\]

The optimal market price, the optimal product’s greening level and the optimal profitability are as shown in Table 1. All the proofs of obtaining the equilibrium results are presented in Appendix.

---

**Table 1 – Equilibrium results**

</tr>
</tbody>
</table>
Next, we consider the decentralized channel model in which the M and R does no longer take collective decisions, but rather consider themselves as an individual entity to maximize their individual profits. We specifically examine the R-led Stackelberg game model whose sequence of events are as follows. First, the retailer decides its market price \( p \). Then, observing \( p \), the manufacturer decides the level of product’s greening \( g \). To ensure a stable profit level, we assume that the product’s wholesale price \( w \) at which the manufacturer sells the products to the retailer is related to market price \( p \) by \( p = \eta w \) (where, \( \eta \geq 1 \) is a price-coefficient). Here, \( w \) is not a decision variable of manufacturer, but determined by the retailer’s market price \( p \). This is because, in our model, the manufacturer does not have a dominant position, rather the prices are driven by dominant retailer. In addition, for the model’s feasibility, we assume that \( 2b \beta \eta - \alpha^2 > 0 \). We solve this game through backward induction. First, the manufacturer’s optimal greening effort \( g \) is obtained for a given market price \( p \) by maximizing its profit as follows.

\[
\max_{g} \pi_M = (w - c)(a - bp + \alpha g) - \beta g^2 \tag{2}
\]

Second, after obtaining the manufacturer’s optimal greening effort \( g \), the retailer decides on the market price \( p \) by maximizing its profit function as follows.

\[
\max_{p} \pi_R = (p - w)(a - bp + \alpha g) \tag{3}
\]

The optimal prices, greening level, and the profit functions are as listed in Table 1.

**Proposition 1.** In the retailer-led green supply chain, the manufacturer will put positive effort for enhancing the greening level of product when its marginal production cost is lesser than a threshold value, i.e. \( c < \bar{c} \), where \( \bar{c} = \frac{-2a \beta}{4b \beta \eta - \alpha^2} \).

**Proposition 1** shows that the manufacturer will have an incentive to positively increase the product’s greening level only when its marginal production is lower than a certain threshold value. Hence, greening is positive only when the cost is less and not it is possible at higher values.

**Model with manufacturer exhibiting fairness concerns**

In this section, we model and analyze the optimal decisions of M and R when M has fairness concerns. Specifically, the fairness-concerned manufacturer will not only care about its own profit but also compares it with that of the retailer’s. Our primary objective is to investigate the impact of fairness on the level of greening effort and the pricing policies of the supply chain.

**Manufacturer’s decision problem**

Based on the fairness model of Cui et al. (2007) the utility function of the fair-minded manufacturer is as follows.

\[
\text{u}_M = \pi_M - \delta^D [\gamma \pi_R - \pi_M]^+ - \delta^A [\pi_M - \gamma \pi_R]^+
\]

where, \( [x - y]^+ \) denotes \( \max(x - y, 0) \), \( \gamma > 0 \) accounts for relative contributions of the channel players, and \( \delta^D, \delta^A \) are the manufacturer’s disadvantageous and advantageous inequity aversion fairness concern parameters, respectively. The greater are there values, the more the manufacturer is concerned about either type of fairness. According to Cui et
al. (2007) we further assume $\delta^A \leq \delta^B$ and $0 < \delta^A < 1$. Since, it is evident from the several recent studies that the preference for advantageous inequality is much less prominent and not even found in the experimental investigations (Ho et al., 2014, Nie and Du, 2017), we substitute $\delta^A = 0$ in the above utility function and replace $\delta^B$ simply by $\delta$ and $0 < \delta < 1$, thus, we get the manufacturer’s decision problem as follows.

$$\max_g u_M = \pi_M - \delta[y\pi_R - \pi_M] = (1 + \delta)\pi_M - \delta \gamma \pi_R$$ (4)

**Retailer’s decision problem**

Next, after obtaining the manufacturer’s optimal greening effort ($g$), the fairness-neutral retailer will decide the retail price ($p$) by maximizing its profit function as defined in Equation (3). After solving through backward induction approach, we obtain the equilibrium results as shown in Table 1. We now analyze the impact of manufacturer’s fairness parameter ($\delta$) on the optimal pricing and greening policies in the following section.

**Influence of fairness concerns**

We propose the following propositions on the basis of our analysis.

**Proposition 2.** In the retailer-led green supply chain with manufacturer’s fairness concerns, the manufacturer will put positive effort for enhancing the greening level of product when its marginal production cost is lesser than a threshold value, i.e. $c < \bar{c}_f$,

where $\bar{c}_f = \frac{2ab}{(4b\beta\gamma - a^2)(1 + \delta)^2 + a^2\gamma \delta (\eta - 1)}$.

Comparing the results of Proposition 1 and 2, we get that in the R-led GSC with manufacturer’s fairness concerns, the threshold value of the marginal production cost required for the positive greening effort by the manufacturer is lesser than that of its corresponding value in the R-led GSC without the manufacturer’s fairness concerns ($\bar{c} - \bar{c}_f = \frac{8ab\beta^2 \gamma \delta \eta (\eta - 1)}{(4b\beta\gamma - a^2)(1 + \delta)^2 + a^2\gamma \delta (\eta - 1)} > 0$).

**Proposition 3.** Under the manufacturer’s fairness-concerned green supply chain, the manufacturer’s optimal wholesale price $w^{opt}$, the retailer’s optimal market price $p^{opt}$, and the manufacturer’s optimal level of greening effort $g^{opt}$ all monotonically decrease in the manufacturer’s fairness concern parameter ($\delta$).

**Proposition 4.** Under the manufacturer’s fairness-concerned green supply chain, the retailer’s profit ($\pi_R$) monotonically decreases with the manufacturer’s fairness concern parameter ($\delta$).

Proposition 3 and 4 illustrate that when the manufacturer feels unfairly treated by the retailer, then it will react by decreasing the effort for product’s greening. This will in turn lead the retailer to lower the market price of the product, since the customers are positively sensitive to product’s greening level. This in turn, will affect the retailer’s profit negatively.

**Conclusion**

In this paper, we evaluate the effects of fairness-concerned behavior on the supply chain decisions through a game-theoretic analysis. Specifically, we investigate the impact of
fairness concerns of the manufacturer on the optimal greening and pricing decisions in a green supply chain under manufacturer’s greening initiatives and retailer’s dominance. For this, we formulate a retailer-led Stackelberg game model in a dyadic supply chain setting, consisting of one manufacturer and one retailer. We then incorporate the fairness concerns of the manufacturer, by formulating its utility function according to the inequity aversion model of Cui et al. (2007). Following the backward induction approach, we derive the equilibrium strategies of each channel members and then determine the effects of manufacturer’s fairness parameter on these equilibrium values. We find that the manufacturer’s sensitivity towards fairness will negatively influence both the manufacturer’s effort for improving the product’s greening level and as well as the retailer’s market price and retailer’s profit function. In addition, the retailer’s profit is also decreasing in the manufacturer’s fairness concern. Furthermore, under certain conditions, in comparison to the fairness-neutral channel, in the manufacturer’s fairness-concerned channel, the product’s greening level will be positive for an even lower threshold value of the product’s marginal production cost.

**Contribution/managerial implications:**
The author investigates manufacturer’s fairness concern in a retailer-led dyadic supply chain where the customer’s demand is sensitive to product’s greening level. To the best of our knowledge, there is very little literature on examining the impact of fairness concerns in a retailer-led green supply chain. This paper fills this gap, which is the main theoretical contribution of this study. The results will be useful for the supply chain practitioners in understanding the social interaction behaviours when two supply chain parties interact in a business. For the retailers, the higher fairness concerns of their upstream manufacturer could negatively influence the product’s greening, the retailer’s market price and profit function. Hence, they should be attentive in choosing its retail price, so that the manufacturer does not feel as unfairly treated and keep putting its greening efforts. For the manufacturer, it is seen that too much fairness concerns will result them in getting a lower wholesale price. Also, if they have higher fairness concerns, then should put the positive greening effort only when the product’s marginal production cost is too low.

**Future research**
We suggest the future studies to consider competition at either manufacturer’s or retailer’s level and investigate the influence of peer’s fairness concerns on the greening and pricing decisions. Further, in our study we assume fairness parameter as the common knowledge to both the supply chain partners. Future studies could break this assumption and investigate the similar case information asymmetry about the fairness parameter.

**Appendix**

**Proof of centralized channel game model:**
According to Equation (1), as \( \frac{\partial^2 \pi_c}{\partial p^2} = -2b < 0, \frac{\partial^2 \pi_c}{\partial g^2} = -2\beta < 0, \) and the determinant of Hessian matrix, i.e., \( H = \left( \frac{\partial^2 \pi_c}{\partial p^2} \right) \left( \frac{\partial^2 \pi_c}{\partial g^2} \right) - \left( \frac{\partial^2 \pi_c}{\partial p \partial g} \right)^2 = 4\beta b - \alpha^2 \). For \( 4\beta b - \alpha^2 > 0, H > 0 \) and hence, \( \pi_c \) is strictly jointly concave in \((p, g)\). Setting the first order optimality conditions, i.e. \( \frac{\partial \pi_c}{\partial p} = 0 \) and \( \frac{\partial \pi_c}{\partial g} = 0 \), and solving the equations simultaneously we can obtain the optimal solutions of centralized channel supply chain as shown in Table 1.
Proof of decentralized channel game model without fairness concerns
Following the backward induction approach, we first solve for the manufacturer’s profit function. According to Equation (2), as \( \frac{\partial^2 \pi_M}{\partial \eta^2} = -2\beta < 0 \). Hence, \( \pi_M \) is strictly concave w.r.t. \( \eta \) and has a unique maximum solution, \( \eta^* = \frac{(w-c)\alpha}{2\beta} \) that can be derived through \( \frac{\partial \pi_M}{\partial \eta} = 0 \). We now substitute \( \eta^* \) and \( w = p/\eta \) into Equation (3) and derive the retailer’s market price policy \( (p) \). As, \( \frac{\partial^2 \pi_R}{\partial p^2} = -(1-1/\eta) \left( \frac{2b\beta\eta - a^2}{\beta\eta} \right) < 0 \), hence, \( \pi_R \) is strictly concave in \( p \). Solving \( \frac{\partial \pi_R}{\partial p} = 0 \) will give optimal \( p \) and other results can be obtained further, as shown in Table 1.

Proof of decentralized channel game model with manufacturer’s fairness concerns
According to Equation (5), \( \frac{\partial^2 u_M}{\partial \delta^2} = -2\beta (1 + \delta) < 0 \), hence, \( u_M \) is strictly concave in \( \delta \).

Next, \( \eta^* = \frac{\alpha[(w-c)(1+\delta)-\delta(p-w)]}{2\beta(1+\delta)} \) can be obtained through \( \frac{\partial u_M}{\partial \delta} = 0 \). We now substitute \( \eta^* \) and \( w = p/\eta \) into Equation (3) and derive the retailer’s market price policy \( (p) \). Then, we get \( \frac{\partial^2 \pi_R}{\partial p^2} = -\frac{1}{\beta} \left( 1 - \frac{1}{\eta} \right) \left[ \frac{2b\beta\eta - a^2}{\eta} + \frac{\alpha^2 \delta}{(1+\delta)} \left( 1 - \frac{1}{\eta} \right) \right] < 0 \), hence, \( \pi_R \) is jointly concave in \( p \). Solving \( \frac{\partial \pi_R}{\partial p} = 0 \) will give optimal results as shown in Table 1.

Proofs of Propositions:
Proposition 1
From the equilibrium results of decentralized GSM without fairness concerns as shown in Table 1, we have \( g^{\text{opt}} = \frac{\alpha}{2\beta} \left[ \frac{(2a\beta - a^2 c)}{2(2b\beta\eta - a^2)} - c \right] > 0 \) for \( c < \frac{2a\beta}{4b\beta\eta - a^2} \).

Proposition 2
From the equilibrium results of decentralized GSM with manufacturer’s fairness concerns as shown in Table 1, we have \( g^{\text{opt}} = \frac{\alpha}{2\beta} \left[ \frac{(2a\beta - a^2 c)(1+\delta - \delta Y(\eta - 1))}{2[(2b\beta\eta - a^2)(1+\delta) + \alpha^2 \delta Y(\eta - 1)]} - c \right] > 0 \) for \( c < \frac{2a\beta}{4b\beta\eta - a^2 (1+\delta) + \alpha^2 \delta Y(\eta - 1)} \).

Proposition 3
Taking the first-order partial derivative of \( w^{\text{opt}} \), \( p^{\text{opt}} \) and \( g^{\text{opt}} \) with respect to \( \delta \) respectively, we get:

\[
\frac{\partial w^{\text{opt}}}{\partial \delta} = \frac{-a^2 \gamma Y (2a\beta - c a^2) (\eta - 1)}{2 [(2b\beta\eta - a^2)(1+\delta) + \alpha^2 \delta Y (\eta - 1)]^2} < 0
\]

\[
\frac{\partial p^{\text{opt}}}{\partial \delta} = \frac{-\eta a^2 \gamma Y (2a\beta - c a^2) (\eta - 1)}{2 [(2b\beta\eta - a^2)(1+\delta) + \alpha^2 \delta Y (\eta - 1)]^2} < 0
\]

\[
\frac{\partial g^{\text{opt}}}{\partial \delta} = \frac{-ab\eta Y (2a\beta - c a^2) (\eta - 1)}{2 [(2b\beta\eta - a^2)(1+\delta) + \alpha^2 \delta Y (\eta - 1)]^2} < 0
\]
Proposition 4

Substituting the values of $w^{opt}$, $p^{opt}$ and $g^{opt}$ of decentralized supply chain case with manufacturer’s fairness concern (from Table 1) into Equation (3) and taking its first-order partial derivative with respect to $\delta$, we get:

$$\frac{\partial \pi_R}{\partial \delta} = \frac{-\alpha^2 \gamma (2\alpha \beta - c \alpha^2)^2 (\eta - 1)^2}{8\beta [(2b\beta \eta - \alpha^2)(1 + \delta) + \alpha^2 \delta \gamma (\eta - 1)]^2} < 0$$

The Appropriation of Trust for a Successful PPC Implementation

Abstract

Production planning and control (PPC) systems are deployed to enable the effective management of variation and uncertainty. In spite of the advancement in technology such as big data and artificial intelligence, the complimentary roles of human and system is increasingly apparent. This paper explores the human-PPC relationship from the perspective of trust. This is done by investigating a recent PPC implementation in SME. In relation to this case the concept of trust is explored as a psychological state and it is suggested that trust appropriation is a continuous process achievable through the leveraging of the basis of trust: purpose, process and performance.

Keywords: Trust Appropriation, Production Planning and Control, Action Research

Introduction

For decades, researchers have called for better alignment between the underpinning concepts and the contextual environment in which the PPC (Production Planning and Control) system is to be implemented. The critical role of the ‘socio’ aspect in developing and implementing a practical PPC solution is well highlighted (Brocklesby, 2016; Burglund and Karltn, 2007; Davis et al., 2014; MacCarthy et al., 2001). Some researchers have gone further, highlighting the importance of developing positive human-system relationship in a successful PPC implementation (Fransoo and Wiers, 2008; Higgins, 2001; Jackson et al., 2004). However, the main focus has been on the complementary roles (tasks) of human and system in the decision making process. For a successful human-system relationship design, development and implementation, some researchers have suggested the pivotal role of trust between the human-system relationship (Fransoo and Wiers, 2008; Muir and Moray, 1996). As trust is ‘fluid’ (Hoffman et al., 2013), appropriation is necessary to avoid ‘mistrust’ and ‘distrust’ (Hoff and Bashir, 2015; Lee and See, 2004).

The remainder of this paper begins by reviewing the need for PPC to be developed into a human centred Decision Support System (DSS). This is followed by a review on the construct of ‘trust’ in the human-automation context. Based on the above reviews, the role and importance of trust in the successful implementation of PPC as a DSS will be explored through theoretical argument. The conceptual framework developed will be used as a lens to explore trust and its appropriation in a successful human-system relationship.
This human-automation implementation is in the context of a PPC-DSS system in a rotary moulding environment. Details of the research methodology used is discussed followed by a discussion of the findings before ending with research contribution and potential future research.

**PPC, a human centred DSS system**
The advancement in technology such as Internet of Things (IoT), Big Data and Robotics is reshaping manufacturing industries (Brauner et al., 2019; Brettel et al., 2014). Although automation has enabled data collection, interpretation, decision making and process control (Lee and See, 2004), the role of the human remains critical. A taxonomy has been proposed by Parasuraman et al. (2000) to describe the types and levels of automation. The four primary types of automated system includes information acquisition, information analysis, decision selection and action implementation. An automated system can be designed to fall within single or multiple types (Hoff and Bashir, 2015). Human involvement in an automated system is depicted across a continuum of autonomy levels. This is represented by a scale of 1 to 10 where level 1 refers to system which offers no assistance and level 10 where the system ignores human acting autonomously.

PPC is concerned with managing variabilities and uncertainties in a manufacturing environment as well as the wider implication on the entire supply chain. As the manufacturing strategy moves from standardisation towards customisation, the associated variabilities and uncertainties increases (Cardin et al., 2017; Olhager, 2003). With the increase in complexity of manufacturing environments there are increases the necessity for human intervention (McKay and Wiers, 2001; Nakamura and Salvendy, 1994). This is mainly due to the perception that humans are able to provide a better response in dynamic environments due to their superior flexibility, adaptability and creativity (Parasuraman, 1997). Ultimately, it is the humans who are accountable for and recipients of the decisions made (MacCarthy and Wilson, 2001). This includes accountability for ethical and legal related issues (Brauner et al., 2019; Philipsen et al., 2019). Thus, it is expected that through the development of PPC into a DSS system, the reaction time of humans will be reduced while at the same time improving decision making quality (McGuirl et al., 2006). This places PPC in the mid region of the autonomy scale, requiring partnership between human and system.

The importance of the human-system complementary role has prompted calls to develop PPC into a human centred DSS system (Arica et al., 2016; Fransoo and Wiers, 2008; Higgins, 2001; Jackson et al., 2004; McKay and Buzacott, 2000). Building upon the human roles (HR) in PPC identified by Jackson et al. (2004) and the design and development criteria proposed by Wiers and van der Schaaf (1997) for a DSS in PPC. Yeong and Stratton (2018) proposed a HR-DSS matrix to support the development process. As shown in Table 1, this matrix crosses DSS development criteria with the human roles in PPC. The DSS criteria are (i) Level of Support, (ii) Transparency, (iii) Autonomy, and (iv) Information Presentation. The human roles in PPC are (i) Interpersonal, (ii) Information, and (iii) Decision Making. This taxonomy explicitly requires the boundary between the roles of human and system to be defined. This is useful in both the development of new PPC-DSS and the evaluation of existing PPC-DSS. With reference to Table 1, the quadrants involving ‘Information Presentation’ mainly concern feedback given by system to human. These feedback becomes part of the input to the remaining quadrants to facilitate contextual interaction between human and system.

According to Lee and Moray (1992; 1994), this interaction is determined by the trust and self-confidence of humans. The success of a human-system development and implementation requires the system to reflect the trust of humans in the capabilities of the
system (the automation part). It is also necessary for human self-confidence to be reflected in their ability to use the system manually under ‘uncommon’ situation which requires intervention. The critical role of trust has prompted researchers to call for appropriation of trust in order to reduce misuse, disuse and abuse of a system (Hoff and Bashir, 2015; Lee and See, 2004; Lyons et al., 2017; Parasuraman and Riley, 1997).

**Trust in Human-PPC relationship**

Trust has been explored from various perspectives: psychological, neurological, sociological, organizational, and interpersonal. Based on the above inter-human trust perspectives, a detailed review was conducted by Lee and See (2004) and summarised them into four broad categories: beliefs, attitudes, intentions, and behaviour. By adopting the framework developed by Ajzen and Fishbein (1980), they argued that beliefs, attitudes, intentions and behaviour are distinct. Beliefs offers the information base in which determines attitude. Attitude guides the adoption of intention. Intentions, the willingness to act, are exhibited in behaviour according to the environmental and cognitive constraints faced. Based on the above arguments, Lee and See (2004) proposes to view trust as attitude which connects the four distinct categories in the following way. Trust is the attitude based on the underlying ‘beliefs’. This is manifested in various intentions and behaviours according to the levels of trust.

The definition of trust from their research is “the attitude that an agent [trustee] will help achieve an individual’s [trustor’s] goals in a situation characterized by uncertainty and vulnerability”. By applying this definition of trust to human-system relationship, the authors suggest that trust bridges the beliefs on system characteristics and the intention to rely and use the system. Trust is arguably not a behaviour due to it being one of the many factors which influences behaviour. Other factors could be both external and internal of a person. Internals could be the workload, situation awareness and self-confidence, whereas externals could be company policy or performance measurements (Lee and Moray, 1994; Riley, 1994). According to this definition, trust only comes into play if trustor is dependent on the trustee to complete certain functions of relevance to trustor’s goals.

![Figure 1: Appropriation of Trust and HR-DSS (Adapted from Lee and See (2004))](image)

Due to trust is between beliefs and intention, any mistrust and distrust will result in negative or unwanted intension, i.e. unwillingness. ‘Mistrust’, also known as ‘over-trust’, occurs at instances where level of trust exceeds actual system capabilities. ‘Distrust’
refers to the phenomena where trust is below the system capabilities. As shown in Figure 2, the ‘level of trust’ and ‘system capabilities’ are represented by Lee and See (2004) in a two axes chart. A diagonal line is drawn in between to depict the appropriated trust, where ‘level of trust’ matches ‘system capabilities’. The region above and below the diagonal line represents ‘mistrust’ and ‘distrust’ respectively. ‘Mistrust’ results in ‘misuse’, whereas ‘distrust’ results in ‘disuse’ of a system (Lee and See, 2004; Parasuraman, 1997).

With the perspective that trust is dynamic (Hoffman et al., 2013; Lee and See, 2004; Lewandowsky et al., 2000), trust needs to be appropriated. This is also known as trust calibration (e.g. McGuirl and Sarter, 2006), trust repair (e.g. Quinn et al., 2017; de Visser et al., 2018) or trust restoration (Philipsen et al., 2019). In the appropriation of trust concept proposed by Lee and See (2004) apparently assumes automation (system) to be static in its capabilities, represented by the appropriation of trust occurring outside of automation (system). In the development and implementation of PPC into a DSS system using HR-DSS matrix, as shown in Figure 1, it is proposed that automation (system) to be included as part of the trust appropriation process (McGuirl and Sarter, 2006).

In the context of implementing PPC-DSS system as an intervention in a company, it is not the purpose of this paper to debate the taxonomy of trust. However, the above discussion highlights the critical role of trust and the need to appropriate trust in a human-PPC relationship. With reference to Figure 1, to effectively appropriate trust, it is necessary to address the ‘belief’ stage of this cycle. This is also known as the basis of trust. Based on a review by Mayer et al. (1995), the general basis of trust in inter-human relationship has been described as Ability, Integrity, and Benevolence. In human-automation relationship, Lee and Moray (1992) describes the general basis as Performance, Process and Purpose. The resemblance in both have been highlighted by Lee and See (2004): Ability-Performance, Integrity-Process, and Benevolence-Purpose. To strengthen the three general basis of trust proposed in human-automation, they reviewed thirteen other research conducted on basis of trust and discovered each of them falls into one of the three categories.

In the context of PPC-DSS, performance refers to both present and historical information relevant to the competency of PPC-DSS in achieving human’s goals. It captures the information related to what the automation does. This information encompass the subjective human-PPC-DSS interaction and experience. Process, in the context of PPC-DSS refers mainly to the algorithms and management philosophy, which underpins the behaviour of PPC-DSS. This centres on the issue of how PPC-DSS works.
The third basis: *purpose* refers to information related to *why* PPC-DSS is developed. This is related to the designer or originator’s intent.

The approach of appropriating trust by targeting ‘belief’ stage is also adopted by de Visser et al. (2014). Based on this, they proposed a trust cue taxonomy to conduct trust assessment on trust agents. In the context of PPC-DSS development and implementation, it is posit that HR-DSS matrix is able to be used to facilitate trust appropriation. As shown in *Table 1*, the *purpose* of the PPC-DSS is represented by considering the Level of Support (S) offered to accomplish the human roles in PPC. The concern on *process* is addressed by looking into the *transparency* and *autonomy* of the system in fulfilling each human role. Through *information presentation* and *level of support* exhibited, *performance* of the system can be evaluated.

*Table 1 – HR-DSS Matrix and Basis of Trust (Adapted from Yeong and Stratton, 2018)*

</table>

The above conceptual discussion provides an insight on the potential role of *trust* and its appropriation for a successful PPC-DSS implementation. It is also the purpose of this paper to explore the relevance of *trust* and its appropriation in real life PPC-DSS implementation.

**Design/methodology/approach**

This research is based on a recent successful PPC implementation in an SME rotary moulding company, Company A. Simplified-Drum-Buffer-Rope (S-DBR), the latest Theory of Constraints (TOC) application for Make-To-Order (MTO) manufacturing environment (Schragenheim and Dettmer, 2000) was adopted. The PPC implementer, who worked as a business system architecture designer, was also a researcher pursuing professional doctoral degree. The dual purpose of this project has prompted the use of action research (AR) to capture practical knowledge in both ‘technical’ and ‘socio’ aspects (Coughlan and Coghlan, 2016; Shani et al., 2008). This two years project was divided into pre-change (determine context and purpose, constructing and planning action), in-change (taking action), and post-change (evaluating action) stages. Data was collected via formal and informal meetings/discussions, job shadowing, observation of actual practice, direct communication with people, and company archival data. As trust is defined as a psychological state in this research, trust level is interpreted by analysing verbal expression and the actual usage of system.

**Findings**

A contextually redesigned S-DBR based PPC has been successfully developed and implemented (Yeong, 2019). Of the various AR cycles in each project stage (pre-change, in-change and post-change), a few AR cycles from in-change is used to explore trust appropriation.

**AR Cycle 1**

To explore and exploit potential CCR (Capacity Constraint Resource), there were attempts to arrive at a detailed scheduling of potential CCR. To achieve this, it is desirable
to capture every possible machine-mould configuration. Senior management has expressed the intention to develop PPC into a strict directive tool to monitor performance of personnel. However, the researcher finds that it is impractical and impossible to code every possible scenario in this dynamic and complex environment where tacit knowledge and human intervention is necessary. From the perspective of purpose, shop floor personnel felt threatened by the presence of the system. It is seen as a monitoring tool which will cause them their job. In addition, process of the proposed system is deemed impractical which cast doubt in the performance expected. Coupled with the bad experience with old manufacturing software which produces job tickets and pushes jobs onto the shop floor with unrealistic delivery date, comments such as ‘the computer [PPC-DSS] system will never work’ is often heard.

**AR Cycle 2**

Informed by the management philosophy of S-DBR, which proposes light planning and heavy execution, it adopts the concept of buffer management (BM) to provide visual and easily understood signals to user (refer to Figure 3a). Each work order is represented by BM colour. Through these colours, work orders are prioritised, expedited and escalated. For continuous improvement purposes, it has the function of targeting (Stratton and Knight, 2009). Efforts are done to develop heuristic algorithm based on tacit knowledge and modus operandi under normal situation. The concept of planned load (PL) is used to represent outcome of tacit knowledge in a visual way (refer to Figure 3b). Multiple improvement cycles were done to obtain confirmation from shop floor personnel on the practicality of the heuristic algorithm and information presentation (process and performance). The use of BM and PL and its representation suggest the PPC-DSS system as only giving feedback and suggestion, without dictating the final decision (purpose). In the process, it increases the trust level of shop floor personnel, evident from their participation to share tacit knowledge and validate the outcome.

![Figure 3: Illustration of: (a) Buffer Management and (b) Planned Load](image)

**AR Cycle 3**

Although the outcome of AR cycle 2 has gained trust, it is still a supplement to existing manufacturing process. The machines do not have any data input/output (I/O) interface, an interface is necessary to capture the final decisions made in resource allocation and work order progress updating. Feedback information is critical for the PPC-DSS system to suggest solutions, such as promised due date in customer enquiry stage. The human role (HR) is evaluated in the context of company business process flow. As demonstrated in Figure 4, PPC-DSS and its associated interfaces are developed and integrated into the
business flow of company, from pre-sales to post-sales. This further enhance the *purpose*, *process* and *performance* of the system to increase human trust level towards the system.

![Diagram of business flow](image)

**Figure 4: Integration of PPC-DSS into business flow of Company A (Yeong, 2019)**

![Diagram showing AR cycles](image)

**Figure 5: Selected In-Change AR cycles to demonstrate trust appropriation (Yeong, 2019)**

From the above findings, trust appropriation is shown to be a continuous process. In this case, it began in the *distrust* region. Firstly, PPC-DSS with flexibility to customise according to contextual requirement places automation system into the trust appropriation process, as shown in Figure 2. This offers opportunities to improve trust level. Secondly, it demonstrates how enhancement in the capability of PPC-DSS is able to increase trust level. In this research, the PPC-DSS enhancement is done in accordance
to human requirements and tacit knowledge, acquired through AR cycles. Thirdly, not necessarily proportional amount of PPC-DSS capability increase will be translated to equal amount of increase in trust level. Based on the trust appropriation concept proposed by Lee and See (2004), Figure 6 attempts to illustrate the trust appropriation process through the AR cycles discussed. The increase in automation capability, $\Delta c_a$ is lesser than from AR cycle 2 to 3, $\Delta c_b$. However, the trust gained from the later, $\Delta t_b$ is higher than earlier AR cycle, $\Delta t_a$. Finally, the PPC-DSS system in company A is being made known to be ‘improvable’. Rather than being treated as a ‘sacred cow’, or requires immense cost or resources to amend, it is able to be improved according to contextual requirements.

![Figure 6 – Trust Appropriation illustration for AR cycle 1, 2 and 3](image)

**Conclusion**

This research attempts to explore the role of trust and its appropriation in the design and implementation stages of PPC. By borrowing the literature from trust in automation, it is used as lens to reflect on a recently completed development and implementation of a human centred PPC-DSS system in an MTO company. In the context of PPC-DSS, the existence of such a system is to assist humans to better manage variability and uncertainties. By adopting the perspective that trust is a psychological state, it is suggested that trust can be appropriated by influencing the three aspects of trust: purpose, process, and performance. Through reflection on the selected AR cycles, it is suggested that trust appropriation is a continuous improvement process. This is made possible with the inclusion of PPC-DSS customisation as part of the trust appropriation process. In other words, the possibility of adjusting PPC-DSS capabilities contributes positively towards trust appropriation. Trust has captured the attention of researchers in the area of automation (for example: driverless vehicles, nuclear plants and flight system). Further research could be conducted to explore the significance of trust appropriation in PPC-DSS adoption and implementation. This may potentially narrow the gap between PPC theory and practice. In real life PPC-DSS implementation, it is not isolated from organisational related context. This implies that trust and its appropriation process might be influenced by other factors which requires further research.

Abstract
Corporate social responsibility has been recognised as a critical business function and capability to improve business performance and competitive advantage. Whilst many organisations accept this, the majority of them failed in implementation, even including large conglomerates such as Target, 3M and Walmart. The lack of standardised procedures for implementation has prompted this study to explore different tools, practices and mechanisms deployed to contribute to CSR integration. Due to the exploratory nature of this study, in-depth case study was adopted to determine what leadership and employee engagement practices and tools have been adopted which allow organisations to institutionalise CSR.

Keywords: Corporate social responsibility, Leadership, Employee engagement

Introduction
As evidenced in the literature, corporate social responsibility (CSR) has evolved from environmental regulation to a more social focus until today where a new form of ‘strategic CSR’ has emerged. CSR has become a form of strategic investment to enhance business image and to improve organisation performance. It is believed that to attain the level of competitive advantage as a result of CSR, a coherent CSR strategy should be outlined rather than having numerous disparate, ad-hoc CSR programmes and initiatives (Rangan et al., 2012). For a firm to drive real social impact and to influence positively on the long-term competitiveness, CSR should be strategized and implemented well from the core of the business. Longoni and Cagliano (2015) supported this view and suggested that all organisations, regardless of the differing expectations imposed upon them, should outline in their corporate strategies and then execute them at functional levels throughout organisations. A report by Deloitte (2017) also highlighted that CSR can be used to get the edge in business and can help firms gain competitive advantage through various possibilities, i.e. being an employer to choose the most talented individuals, being able to access the best types of finance, and having high quality supply chain partners. Unilever is a prime example of a firm which has used these social and environmental issues as a means of creating a business advantage.

To achieve the intended objectives of CSR, there is a need for a planned process with strategic applications to the organisation mission and overall aims (Carroll & Shabana, 2010; Porter & Kramer, 2011). In formulating CSR as part of a firm strategy, organisations need to determine specific priorities and to establish immediate steps and goals. It sets out a detailed action plan on how the organisation will involve its corporate activities in developing value for stakeholders, thereby
achieving its corporate objectives (Emezi, 2015). It must be considered that CSR and sustainable development are moving targets that cannot be achieved as a one-off but must continuously be reviewed and updated, therefore this strategy should be reconsidered regularly, along with the finance strategy, HR strategy and marketing strategy (Slack et al., 2015). During the strategy review, managers must be open minded to add new priorities into business strategy and objectives where these may emerge (Kaplan and Norton, 2005). But the real challenge is to move beyond the rhetoric and ideology of CSR and to build it into a core capability of the organisation (Maon et al., 2009). Once CSR has been established at a strategic level, how to bridge the gap between CSR formulation and implementation then must be addressed (Engert & Baumgartner, 2016). Despite an abundance of CSR literature, the proliferation of CSR approaches and implementation are often unclear, confusing and lacking in uniformity (Bucur, 2013; Asif et al., 2013). There is a knowledge gap existing in understanding best practice of how to translate senior management commitment to CSR initiatives and how to implement CSR to all levels of the organisation. Therefore, this research will explore how leadership and employee engagement practices can contribute to the internal implementation of CSR in practice. In details, the research aims are 1) to identify leadership practices which positively affect the internal CSR implementation; 2) to determine employee engagement activities utilised to facilitate CSR integration; and 3) as a result of the findings, to make practical and knowledgeable recommendations to a framework for communicating mission and values to all employees (internal communications strategy) in a way which would help their companies to meet CSR targets.

The reminder paper is structured as follows: next section examines CSR literature, which is followed by highlighting the research design and research methods on case studies applied for this project. Research findings are presented with detailed discussion and implications. The paper closes by drawing conclusions and highlighting contributions in the final section.

**Literature Review**

Corporate Social Responsibility (CSR) initiatives have gained considerable momentum since post –World War II as companies increasingly engage in globalised activity which has interwoven both business and society together. CSR has evolved from simply doing good deeds for society in 1950s (Friedman, 1970), to a universally approved concept which has become an important, innovative, strategic management issue in the 21st century (Moura-Leite and Padgett, 2011). It is no long a legal requirement imposed upon companies, but also deeply rooted in the concept of sustainable development (Málovics et al. 2008). Due to this increasing need to merge economic growth and social responsiveness, there has been an emergence of CSR literature and research. CSR has become a key subject in both business practice and academia. For a firm to drive real social impact and to have positive impact on the long-term competitiveness, CSR should be strategized and implemented well from the core of the business (Porter and Kramer, 2002).

Despite an abundance of CSR literature, the proliferation of CSR implementation are often unclear and lacking in uniformity (Asif et al., 2013). Whilst almost all organisations can create a CSR strategy, few can move beyond the stated aims and intentions written within it, to implement objectives into effective actions and results (Orlitzky et al., 2011). It was stated that there is lack of attention on methodological and practical CSR implementation, despite the effort to the implications of CSR practices in relation to business strategy (McWilliams et al., 2006). Companies is lack of understanding of how CSR strategy penetrates the entire firm by migrating from a strategy to operations. This can also be attributed to the fact that there is no one-size-fits-all approach to the institutionalisation of CSR. Thus, there is widespread failure in CSR implementation due to the inability to develop management solutions internally and to systematically integrate CSR into business operations (Gond et al., 2012). Knowledge gaps also exist due to the emphasis on larger and international firms, and the importance placed upon the relationship between social and financial performance instead of focusing on CSR antecedents and the processes of integrating it into an organisation, consequently providing little empirical evidence (Perrini and Minoja, 2008; Johnson, 2015). Research shows that even today large
companies such as 3M, Target and Walmart miss some of their CSR targets due to implementation failure (Ward, 2014).

How organisations strategize and implement their CSR practices will differ in relation to the requirements from different stakeholders. These requirements vary depending on the organisation, industry and country which the firm is operating within. However all firms should engage not only in external CSR practices, but also internal. In fact organisations increasingly recognise that they affect employees, workers, customers and local communities through their internal business operations, whether directly or indirectly and proactively decide on the best way of managing this. Some examples of internal CSR practices include workplace health and safety, reducing unsociable working hours, employment practices, training programmes. However in the CSR literature, there is a knowledge gap in understanding best practice of how to internally implement CSR and how to translate senior management’s commitment to CSR initiatives to staff at all levels of the organisation. Therefore, this research is to investigate how CSR can be implemented throughout the organisation. This research investigate the two key factors- leadership and employee engagement. This research potentially contribute to make practical and knowledgeable recommendations to create a framework for communicating mission and values to all employees (internal communications strategy) in a way which would help their companies to meet CSR targets.

**Research Method**

*Research Strategy*

A case study was adopted for this research. It allows the researcher to analyse contextual conditions which were highly pertinent to the phenomenon of internal CR. It was also useful in establishing behavioural conditions through the individual’s perspective and explaining the complexities of real-life situations that often are not captured through experimental or survey research. The in-depth case study is undertaken on three business organisations to explore from a holistic view of each of these organisations. Yin (2009) supports that the use of multiple case sources of evidence provides data triangulation, increasing the validity of the research. It allows for cross-case analysis as well as within case, to check if phenomenon remain the same in other organisations. It is acknowledged that while making generalisations based on such a small number of cases can be difficult, these differences have been minimized by selecting organisations with similar characteristics to increase the generalisability of the study (George & Bennett, 2005).

Three organisations were selected from Northern Ireland. based on their similar orientation and commitment to CSR as they have all been awarded BITCNI’s CORE accreditation. CORE is the standard in Northern Ireland for responsible business. CORE accreditation to date has been awarded to twenty-three organisations (BITCNI, 2017). The three organisations which were chosen to represent a cross-section of the Northern Irish industry are a public services firm, a manufacturing company and a privately-owned retail company. Two of the organisations are SMEs whilst one was chosen as it is a franchise of a multi-national enterprise, with de-centralised operations. The selection of the third company offers the opportunity for comparison with the other two Northern Irish founded companies and the possibility to highlight any similarities or divergences. The comparative framework of this study and the firms’ similar characteristics allows for cross validation of results and increases the potential to make industry-wide generalisations.

*Data Collection*

In-depth case studies were conducted via various data collection methods. Interviews were undertaken within the case company with a mixture of both senior and junior members of staff through cross sections to gain a comprehensive and representative perspectives. A semi-structured interview framework was implemented, whereby the researcher prepared the same set
of questions to be answered by all senior staff and a separate but identical set of questions for all junior staff. Documentary analysis was undertaken to consolidate and contextualise data collected from the interviews. This method has been used in reviewing the internal CR communications techniques of all case organisations, by collecting their applications for CORE accreditation, quarterly magazines, weekly newsletters, mail updates and other company specific communications. Access to organisations was granted which allows observation to be undertaken within each of company. The researchers has been in the company on a weekly base. The researcher and employees established a relationship of mutual trust and confidence to develop a favourable relationship, ensuring that field research was both theoretically desirable and practically possible (Saunders et al. 2015).

Data Analysis
In this study, the thematic analysis technique was used to conduct interview analysis. Analysis followed the three steps suggested by Miles and Huberman (1994) for data reduction, data display and data conclusion. The data was first reduced to quotes, sentences or paragraphs which were relevant for answering research questions, known as first-order codes. Then the data was analysed and separated into second-order codes. Descriptive categories were then deduced from the second-order codes such as ‘CSR strategy’, ‘organisational structure’ and ‘values’. These categories were then coded into different sub-themes which represent the different phases of implementation of internal CSR as highlighted by the interviews.

When the results underwent thematic analysis, different sub-themes emerged and the practices identified were categorised within these. Analysis of these interviews revealed many different constructs and internal mechanisms to support internal CSR implementation. The results have been synthesised into three separate phases, otherwise known as sub-themes, namely (i) Before implementation (ii) During implementation (iii) Ensuring future implementation, to better understand the role of leadership and the impact of employee engagement contribution to CSR implementation. Detailed findings have been summarised and broken down into the sub-themes and categories which fall within each sub-theme to identify the common features of management and employee engagement contribution.

Sub-theme 1: Before implementation- before an organisation can fully implement internal CSR, there are prerequisites which are essential to facilitate successful implementation. This research has found that during this phase, leadership plays a critical role in contributing to the development of these mechanisms that act as antecedents to CSR implementation. During this phase, leadership must consider: strategy, organisational structure and value.

Sub-theme 2: During CSR implementation- once the prior foundations have been laid by leadership for CSR implementation, the next step is to get employees on board and to engage and encourage them to participate. Employee engagement for implementation have been identified from the case organisations are employee voice, employee involvement and support.

Sub-theme 3: Ensuring CSR implementation- for CSR implementation to reach its fullest potential, this research highlight that leadership must take necessary steps to keep the momentum going to ensure that CSR does not occur as a one-off activity but rather integrate into the life and soul of the organisation on communication, training and culture.

Findings and Discussion
Concurrent to the literature, all companies interviewed in this study did not have a step-by-step implementation programme in place for translating CSR from a top level management to an operational level. Whilst all three organisations were found to have moved from an ad-hoc approach to CSR to a more strategic approach, they still do not have explicit implementation steps. The exploratory interviews in this study covered two significant issues: different steps the organisations proceeded for CRS implementation and the practices they adopted on leadership and employee engagements. There are three main phases presented in Figure 1.
Phase 1: Before CSR implementation
This first phase is essential as it acts as a facilitator to underpin all CSR activities which are undertaken in the organisation. The purpose of the first phase has been recognised to establish the correct antecedents that will propel CSR implementation throughout the organisation. The companies under this study all mentioned the importance of similar second-order codes in implementing CSR which fall under the categories of CSR strategy, organisational structure and company values.

Strategizing CSR - all three case companies had in place a clear CSR strategy. Whilst they had begun implementing CSR on ad-hoc basis, in recent years they have all recognised the importance of building a specific strategy. These findings were not surprising as the literature holds that many companies find it easy to formulate a CSR strategy (Longoni and Cagliano, 2015). However, unlike the majority of firms, the case companies did not stop at developing a strategy but their management discussed how they established specific targets and developed measures to ensure these targets were being met or to investigate why not. One organisation used the balance scorecard approach to measure CSR performance within the context of overall firm performance and to gauge how well it was being implemented. Conversely, the two other case organisations developed targets and measures based on performance from previous years and measured these against one another. The important factor here is that despite the different measurement systems, all of the companies seriously measure their progress.

Organisational structure - organisational structure can be an effective tool as it acts as a medium through which CSR strategy can be recognised internally as a priority. All three case companies had changed their organisational structure over the past five years to reflect the changes of their ad-hoc approaches to CSR implementation and to display their commitment to CSR implementation. All of them stated that how they had developed new roles specifically to delegate responsibility to individuals. Company A has developed a CSR committee, made up of twelve individual operational staff who are responsible for communicating CSR initiatives to the rest of the organisation, and a member of the senior management team member who sits on this committee to give support and guidance. Company B developed a team called SENSE to develop a name for CSR within the organisation. Contrastingly, Company C, does have a centralised team dealing with CSR at the company’s headquarters but it is different at a local level. Whilst they previously appointed individuals to be responsible for CSR, now they removed the roles and created a culture where the whole workforce work together to achieve CSR. This result was surprising, as it differed in contrast to Companies A and B, therefore it would be interesting to investigate and monitor how the eradication of this role will influence CSR implementation in Company C over the course of time.

The interviews also highlighted that the case organisations tend to have flatter organisational structures whereby encouraging participative leadership. Organisational structure was found to act as another antecedent to CSR implementation as it plays an important role in influencing patterns of communication and decision-making (Huang et al., 2011). It decides how power and responsibility within an organisation will be allocated, as well as how tasks will be divided and coordinated throughout the company (Daft, 2004). Delegating decision making and responsibility...
to employees in more horizontal organisations has found to increase job satisfaction as individuals’ higher needs are met as they achieve autonomy and self-realisation (Ghiselli & Siegel, 1972). Amongst some of the larger companies who have the best CSR reputations, i.e. Sony and Google, are also known for their flat organisational structure (Smith, 2017; Sony, 2017). This effectively allows for better information sharing and encourages innovation from more satisfied employees.

Values - in almost all the interviews, values were mentioned signifying the importance that they hold not only at a firm level, but also at an individual level. A common theme was ensuring that everyone was aware of the company values to promote the same goals, whilst understanding what the company holds to be important. The importance of training new employees in organisation values was highlighted too. Company A established that when recruiting a new staff member, the compatibility of the individual values were more important than their skillset. The interviewee claimed that the interview was 60% values and 40% skill, as they believed that it would be easier to upskill a new recruit than to shift their values. She remarked how it is important for their company to recruit individuals whose values are aligned with the company’s. Another important factor uncovered in the research was the desire to transfer the company values to third-party contractors and agency staff. Company A and Company B explained how these individuals also received training about their organisation values and both companies stated that they saw these groups as an extension of their family of employees, contributing to the CSR implementation as much as the direct workforce.

In general, at this stage, the antecedents to good internal CSR implementation rest upon the leadership. How well a firm can build a CSR strategy, make effective organisation structural changes and instil the company values, is the responsibility of top manager and depends on how competent they are in carrying out these practices to facilitate company-wide implementation. Thus, leadership is vitally important in CSR implementation. In accordance with the literature review, the findings suggest that a transformational leadership approach is found within the research to be the most appropriate for engaging and energising staff because the leadership team are able to offer a purpose which transcends the short-term goals. This agrees with the Conger and Kanungo’s (1998) findings and also upholds Stone et al.’s (2003) work that suggests through shared vision and values of the leadership team with employees, followers will be energised and in turn will take responsibility for creating the new reality.

Phase 2: During CSR implementation

Although leadership may drive the underlying mechanisms which facilitate CSR implementation, the actual process of implementation must also be driven by the workforce itself. Therefore, the purpose of the second phase is concerned with getting employees to partake in CSR activities and to work towards CSR implementation. For employees to do so, they must be motivated and engaged in their job role. To drive CSR implementation which produces greater value for business and society, a developmental model of engagement is required as established by Mirvis (2012). The research undertaken has uncovered similar tools and approaches used by the three case companies to engage employees in CSR, including employee involvement, employee voice and support.

Employee involvement - the interviews highlighted that all the case organisations encouraged direct employee participation for a more meaningful attachment to CSR implementation. In the three organisations, employee involvement ranged from operational staff acting as instructors at open days, giving demonstrations, delivering briefings to school children, volunteering in the community, recycling, meeting external stakeholders and participating in community projects. In many instances, allowing employees to take the lead on these activities energised them and delegated responsibility. In all case organisations, leadership was able to capitalise on the special skills of the employees and use these to engage employees in CSR activities and simultaneously achieve CSR implementation.

Through the empowerment of functional level employees and giving them authority to make
CSR decisions and to participate directly in CSR activities, some of the interviewees mentioned that they felt a great sense of reward and satisfaction in knowing that they had helped and were able to contribute and specified that they would want to do these types of activities again. These findings are similar to the research conducted by Assen (2016) who found that empowered leadership in the field of lean management across the organisation. The situation with CSR implementation is similar as the delegation of responsibility increase employees’ job satisfaction which cultivates employee interest and dedication, thereby encouraging participation and contribution to CSR implementation.

Employee voice – this research revealed that all three companies were particularly interested in ensuring that employees have a voice within the company. Company A has a formal mechanism in place to facilitate this, whereby all employees have the ability to anonymously put forward any suggestions that they have to the ‘Right Track Team’. The suggestions are all put forward and once a week, leadership review these and make any changes as suggested where possible. Gestures such as these allow for employees to feel valued and listened to. Another formal mechanism Company A has in place, is a ‘High 5’ mail chain where every month staff can give recognition to each other in an email that is passed around the entire workforce. In doing so, it recognises the effort and hard work of employees and energises them in their work environment. Company C has a formal mechanism which is an employee survey, internally known as Voice, which is distributed to all employees which gives them the space to make suggestions and recommendations for the workplace. Company B also highlighted that they have previously tried to do employee surveys, however it was difficult to complete because of the nature of the industry in which it operates and that they found it impractical as not everyone has access to an email address, thus it is difficult to ensure all staff return a completed survey. This research also revealed that all three companies are good at engaging employees by providing informal mechanisms. Company A has opened a new common room with games and a coffee machine, they often have ‘Feed Your Face’ Fridays where everyone comes together and in these ways, there is opportunity for leaders and staff to come together and have the opportunity to be seen and heard. However, a problem is that Company B uses only an informal approach in establishing Employee Voice, whereby every Friday morning. They do not appear to have any anonymous forum through which employees can make suggestions which may prevent organisational learning or lead to unresolved problems if the employee does not feel comfortable discussing these face-to-face (Detert & Burris, 2016), which could hinder the internal implementation of CSR.

Support - evidently employees are engaged and will participate if they are empowered and feel that they have the support from the top management team. Many of the interviewees at the functional level mentioned that their managers were mostly visible, or even on days where they were not. They feel comfortable in approaching them on a formal or informal basis. In Companies A and C, employees all noted that leadership were approachable due to the open-door and open-plan office environment. Hongisto et al. (2016) provided experimental evidence to suggest that there is a relationship physical environment and employee satisfaction. Their results found that the conditions of an open-plan office could improve employees’ job satisfaction, making employees more likely to be engaged in their work. In this way, the open-door policy facilitates employee engagement to enable the workforce to better work towards CSR implementation. The visibility and approachableness of the leadership team increases the employees’ Perceived Organisational Support (POS), (Einsberger et al., 1986) and allows employees to feel like they are highly regarded and valued by their employer. This POS is also linked to employee commitment, therefore if leadership fosters a higher level of POS through increased visibility and access, employees’ in-role and extra-role behavioural performance is likely to increase simultaneously. As leaders are more approachable, they gain the confidence of employees and boost workforce morale. Company A was the only company to specify that they gave informal recognition every month to employees, through the ‘High 5’ mail chain which was previously
mentioned. This mechanism provides the opportunity for employees to receive credit for work they have done and may help in boosting self-esteem, team morale and confidence across the organisation. This was an exception as the other two cases did not mention any similar constructs. Despite this, it was a tool which the employees were grateful for and gave much positive feedback about, therefore it could be something that the other two firms seek to adopt and implement too.

Phase 3: Ongoing CSR implementation
Organisations do not only need to successfully complete CSR activities to achieve targets established by the CSR strategy for a short time period, but also to achieve long-term CSR implementation. Thus, whilst the other mechanisms and tools mentioned above act as antecedents to CSR implementation, the purpose of the third phase is to highlight other methods to ensure that the CSR momentum continues advancing and to encourage employees to stay actively engaged and involved in CSR efforts in the long-term. These have been broken down into the following categories:

Communication – all three case companies work hard to use a range of communication mediums to keep employees up-to-date about the external CSR initiatives that the company is involved in and to let them know of any new programmes or opportunities that will be available. All interviewees mentioned the importance of two-way communication between employees and leaders, with one interviewee describing it as a “two-way street”. All companies endeavour to open that communication medium in a different way, while Company A ensures a member of senior management team sponsors the CSR Committee by giving valuable feedback, Company B has informal face-to-face meetings between one staff member and one leader every Friday as previously mentioned, and Company C promote this communication from the very outset when all staff are being inducted and they met and get to know all of the senior leaders. One of Company C’s core values is ‘Openness’ which also promotes communication between the two parties. The research highlighted the importance of communicating with employees not just when leaders needed to communicate targets, news or deliver updates about the company, but also on a more personal level and more frequently. Whist many had meetings to deliver information regarding company updates, it is recognised in the literature that workplace meetings provide limited scope for meaningful dialogue which is a defining characteristic of employee engagement, therefore while meetings can be useful for communicating downwards. ACAS (2012) recognises that there should be avenues available to provide upward communication flow to facilitate employees’ capacity to influence higher level management decisions.

Training - advanced training for all employees can foster the ongoing implementation of CSR. In all junior staff interviews, they specified that they received training which was made interesting and meaningful to them. Company B in particular discussed how they often got to choose the different courses that they wanted to attend. An interviewee from Company B specified that if a course appeared and he felt it would be valuable to him, he could approach leadership to be given permission for it. Others commented how the training they received was useful and interesting and helped them in their job role, comparing it to just receiving training for the sake of it. In receiving this training, employees feel better equipped to do their job and it creates intrinsic motivation for them, leading to job satisfaction and better engagement with better job performance (Saks, 2005), which is an enactor of internal CSR implementation. Through ongoing training, employees are upskilled and developed as which consequently should enable leaders to be confident their employees are capable of implementing CSR well. Many of the interviewees mentioned that training was given to third-party agency staff or external partners to ensure that they were aware of values and the commitment to CSR to enable them also to work towards the same CSR goals. This external collaboration is something that should be considered within this third phase in order to develop CSR from an internal level to external to maintain long-term CSR efforts.

Organisational culture - organisational culture appears to be an enactor of internal CSR implementation. Whilst none of the interviewees explicitly mentioned the culture of their
organisations, it was an underlying theme that was deduced from the first and second-order codes. All the leaders interviewed discussed how their organisations are attempting to embed CSR principles into the heart of their business operations and culture so that it CSR is not additional, but rather it will be viewed by employees as something that their involvement depends on (Slack et al., 2015). Apart from the underling values which contribute to the organisational culture, there are additional observable symbols and behaviours which create culture too. All organisations demonstrate similar behaviours as leadership attempt to advocate the message of family and togetherness through the promotion of company days away, open days where the whole family is invited, all of which work to ensure that their staff feel valued, appreciated and part of the organisation. Some of the other activities highlighted across the interviews ranged from putting on a company BBQ, building a bicycle shed for employees, creating a shared common room with games and a coffee machine or opening the facilities to show a football game for all staff. All of these activities demonstrate the values of teamwork, community, family. Another common theme stated by the interviews was the care the leadership teams take to promote the health and wellbeing of their staff. For example, Company A has introduced an email embargo, whereby staff are not allowed to respond to emails outside of working hours and working overtime is frowned upon. Company B have launched new training in mental health as they recognise the high suicide rates in their industry. Company C are also in the process of restricting the number of overtime and weekend hours that employees can work. Promoting staff health and wellbeing signals to employees that their employee cares and increases their organisational commitment. It benefits the employer too as it employees are more likely to be better placed to do their jobs effectively and to be engaged in them as the staff are not burned out, but instead well looked after.

Conclusions
This research has attempted to close a gap in CSR literature by providing empirical research on the exploration of employee engagement practices and leadership practices to find out how they can be used as facilitators of internal CSR implementation. Research undertaken found similar features and mechanisms utilised by all of the three high CSR performing organisations and synthesised these into a logical framework.

In practice, these results could be helpful for other companies who are striving to implement CSR successfully. They could follow the framework and begin to duplicate the practices and mechanisms identified and to develop their own CSR integration. It would be helpful if they could establish measures to report on the progress of their implementation which would indicate how useful and valuable the framework is in practice. It would also be helpful for those companies to share knowledge about their experiences of the use of the model, as this could help increase the framework’s effectiveness. Within the academic field the findings from this research can contribute to the beginning of empirical research to attempt to close the gap in research. Obviously, given the limitations of the study and the small number of case companies in which the research was undertaken, this research will need to be expanded and developed to be able to generalise any findings. However, the in-depth study is a good starting point and give useful opportunities to understand CRS implementation by a holistic view. There is potential for each of the stages of the framework to be explored on a deeper level too, especially the third phase of the model is that which perhaps needs more focus. The third phase of the framework is concerned with maintaining the momentum for CSR implementation in the long term which would be better to conduct future research by different mechanisms longitudinally.

Abstract

The purpose of this paper is to understand organizational behavior concerning quality costs in product development and operations. It aims to contribute to the understanding of the multi-causal interdependencies of quality management on the development process and operational performance, including the quest for an overall appropriate level of cost of quality. After a structured literature review to examine the concept of asymmetric cost behavior and managerial short-termism, findings were merged into a simulation model by using the system dynamics modelling approach. This methodology allows to analyze dynamic consequences of the multi-causal reality of quality management in product development.

Keywords: quality management, asymmetric cost behaviour, system dynamics

Introduction

Although the over-all positive benefit of quality management and approaches such as TQM is generally well understood (Freiesleben, 2005), many organizations do not or only partially implement quality management methods (Prefi, 2014). A reason for this paradox could be that it is difficult to establish direct links between quality methods and operational performance due to multi-causal interdependencies in organizational systems (Jochem, 2014). More concretely, there are doubts that efforts in failure prevention are worth the benefit in terms of quality costs, and costs for failure prevention might even exceed costs of failures (Slack et al., 2016). Thus, organizations fear to not achieve their economic quality goals while increasing failure prevention costs (Boulter et al., 2005).

This uncertainty might lead organizations to overreact, possibly taking short-term decisions and showing behavior in regards of quality costs that will not lead to success (Schiffauerova & Thomson, 2006). When managers (unintentionally, due to organizational pressures, or triggered by incentive structures) concentrate on quick fixes instead of fundamental solutions their behavior can be named short-termism or firefighting (Bohn, 2000; Longenecker et al., 1994).

A less-than-proportional decrease of costs in relation to a decrease of activities has been named sticky costs (Brasch, 1927), an effect that is triggered by the phenomenon called asymmetric cost behavior (Reimer, 2018).
An excessive shortage or increase (e.g. in quality initiatives) of budget and asymmetric cost behavior could cause an upswing of oscillations in costs of quality (see Figure 1). We hypothesize that the developments shown in the figure are caused by two phenomena: (i) asymmetric cost behavior, and (ii) short-termism of managers. In this context, short-termism could result in either cost cutting as well as in exaggerated investment into quality initiatives.

To support this proposition, we performed a short survey by using a single mode strategy (Laaksonen, 2018, p. 30). The survey was designed under consideration of size and order of questions in the field of quality management and quality costs and the use of the Earlier Social Surveys (ESS) Scale (Laaksonen, 2018, pp. 36-39). 133 participants where contacted by mail using the business network LinkedIn. The target population was defined as experienced employees or managers as part of a quality organization in one of the top 100 automotive supplier (Chappell, 2018). The search was performed by using “company name” plus “quality management”, and resulted in 16 valid responses.

Participants had to answer questions concerning quality costs and their estimation about connections between costs of failure prevention and cost of failure. A majority approved a link between failure prevention costs and failure costs but only 21% believe this link is linear or direct. Although most companies are gathering quality costs, only half of the participants confirmed a separate collection of failure prevention costs.

Half of the participants do not believe that managerial behavior in their company is appropriate to changes in quality costs, which can be seen in asymmetric cost behavior or short-termism. A slight majority can see irrational budget cuts sometimes and stronger focus on failure costs than on failure prevention costs. Most participants can see a tendency for an untargeted use of failure prevention funds. Almost 70% believe that short-termism lead to an increase of quality costs in long-term. Finally, a majority of 65 % support the hypotheses of quality cost fluctuation over time.

**Problem description**
A link, even if not direct, between cost for failure prevention and failure costs in operations seems to exist. However, managers seem to either ignore this context or might
have a lack in understanding the interconnections. Activities in failure prevention often seem to be implemented uncoordinated without measuring the result of each activity. That leads to an uncoordinated increase of failure prevention costs to aim for good quality in operations. On the other side short-termism or fire-fighting is still a common behavior which leads to abrupt cost cutting by manager while ignoring long terms effects on quality costs. That might lead to an upswing of overall quality costs and an inefficient managing of quality costs in long-term.

**Research Question and Objectives**

Taking these problems and the hypotheses into consideration, the following research question is formulated:

RQ: What kind of causes or interaction of causes could trigger an oscillation of quality costs accompanied with a steady increase?

The objective of this paper is to understand possible causes provoking the phenomena of oscillation and increasing the overall costs of quality. We aim to build a basic system dynamic model that is able to answer the research question by showing interdependencies and effects of our hypotheses.

**Approach, Methodology and Contribution**

This paper provides a basic literature review for an overview on cost of quality as part cost controlling, asymmetric cost behavior and short-termism followed by the description of our work in progress version of the system dynamics model.

The contribution of this paper is twofold. First, the combined effects of asymmetric cost behavior and short-termism have not been investigated in the context of quality related costs before. Second, we developed a system dynamics model, which comprises the composition of quality costs and their interaction. It might help managers to understand interdependencies within their organizations and will contribute to avoid an upswing of oscillations in costs of quality. The model can be customized for further research in the field of quality management.

This paper might also contributes to transform quality into a measurable quantity, in order to help organization to find the right balance between investment and return on quality costs.

**Literature review**

The literature review has been performed in a dedicated approach (Ridley, 2012, pp. 6-11) clustered by the relevant topics “definition of quality costs”, “concept of asymmetric costs” and “short-termism or fire-fighting by managers”

**Cost of quality as part of quality cost controlling**

Quality controlling is the planning, execution and control of quality-related activities with regard to the economic orientation of quality management (Bruhn & Georgi, 1999). The term cost of quality is defined as sum of all quality related costs in an organization and provides a major key performance indicator (KPI) to evaluate the quality performance of an organization (Jochem, 2014, pp. 28-31). The total costs of quality are summed up by prevention costs (e.g. Q-Planning), appraisal costs (e.g. planned testing, controlling) and failure costs (e.g. scrap and rework) (Schiffauerova & Thomson, 2006, p. 3; Slack, et al., 2016, p. 591). However, there are multiple approaches in categorizing quality costs (see
Table 1) but most of them are based on the prevention, appraisal and failure (P-A-F) model.

**Table 1: Generic cost of quality models**

<table>

</table>

A common model for the categorization of quality related costs in the automotive industry is the model of the automotive association (VDA) which separates between:

Failure prevention costs: Costs for QM-system, Q-planning, planned testing and checking (including appraisal costs), supplier management.

Failure costs: Scrap, rework, claims including costs for warranty and goodwill.

The VDA models includes failure appraisal costs into failure prevention costs (Verband der Automobilindustrie e.V. (VDA), 2015, pp. 8-9). Due to a strong focus of our work on the automotive industry, we preferably use the VDA categorization in our model rather than one of the other common models above.

**Asymmetric cost behavior and Stickiness of costs**

Studies questioned proportional cost behavior and the traditional view of linear or proportional cost behavior was challenged in literature (Reimer, 2018, p. 7). Already in the 1920s, the banking sector showed slowness in the adjustment of labor costs during a recession and first researches started questioning proportional cost behavior (Hasenack, 1925, p. 83). Similar effects in different sectors where identified and the term “remanence of expenses” was introduced (Brasch, 1927, p. 68). Strube (1936) provides a range of sources for the remanence of expenses and introduces the term of “asymmetric cost behavior” as one of these sources (Strube, 1936, pp. 19-21).

In the recent literature, the term remanence of costs is defined as staying behind the changes by an activity level increase and decrease (Guenther et al., 2014). In contrast to the remanence of costs, the term sticky costs is defined as staying behind the changes only by an activity decrease (Malagoli, 1985). Anderson, Banker, and Janakiraman (2003) defined costs that decrease less for activity decreases as they increase for an equivalent activity increase as sticky costs and they described this phenomenon as asymmetric cost behavior (Reimer, 2018, p. 9). The work of Anderson, Banker, and Janakiraman (2003) is focusing on Selling, General and Administrative Expenses (SG&A) costs in relation to revenue. The evidence of cost stickiness is given when the change of SG&A costs with a revenue increase is greater than the change for revenue decreases (Reimer, 2018, p. 18).
Sources of cost stickiness are diverse but can be divided into two major groups, intended management decisions and unintended management decisions (Malagoli, 1985). Reimer (2018) as one of the most recent authors dealing with asymmetric cost behavior defined several dimensions of cost stickiness (Figure 2).

The most analyzed and discussed drivers for cost stickiness are economic sources, management behavior and agency problems (Anderson et al., 2003, p. 48). Changes in economic conditions might cause an adjustment of costs by managers as a result of a rational deliberate decision aimed on long term targets and therefore provides an example for the category of economic sources (Reimer, 2018, p. 11). A behavioral source could be overconfidence of managers who tend to overestimate future sales and therefore do not adjust redundant resources in response to a sales decrease which then can lead to cost stickiness (Chen et al., 2013). Self-interested managers who tend “to build their empire” by increasing their division size providing an example for agency problems (Reimer, 2018, p. 14).

The model of Weiss provides a firm- and period-specific measure of cost stickiness (Reimer, 2018, pp. 20-21). The model includes the costs and sales changes of a company’s last four quarters, where the calculation evaluates changes in the most recent quarter. For the selected quarters, Weiss proposes to calculate the differences of the logarithmized ratios between cost and sales differentials (Reimer, 2018, p. 20). The logarithmic measure is motivated by comparability across firms and mitigation of potential heteroscedasticity.

\[
(1) \quad STICKY_{i,t} = -\left[ \log \left( \frac{\Delta \text{Cost}}{\Delta \text{Sale}} \right)_{i,\tau} - \log \left( \frac{\Delta \text{Cost}}{\Delta \text{Sale}} \right)_{i,\bar{\tau}} \right] \quad \text{with } \tau, \bar{\tau} \in \{t, ..., t-3\},
\]

Where \( \tau \) is the most recent period of the last four periods with a decrease in sales and \( \bar{\tau} \) is the most recent of the last four quarters with an increase of sales, \( \Delta \text{Sale}_{i,t} = \text{Sale}_{i,t} - \)
$Sale_{i,t-1}$ and $\Delta Cost_{i,t} = (Sales_{i,t} - Earning_{i,t}) - (Sales_{i,t-1} - Earning_{i,t-1})$. A lower value of STICKY implies a higher level of sticky cost behavior (Reimer, 2018, p. 20).

**Short-termism or fire-fighting by managers**

Short-termism describes an excessive behavior in decisions and outcomes that focus on short-term results at the expense of long-term interests (Graafland, 2016, p. 127; Laverty, 1996, p. 831). When managers (unintentionally, due to organizational pressures, or triggered by incentive structures) concentrate on quick fixes instead of fundamental solutions their behavior can be named short-termism or fire-fighting (Bohn, 2000; Longenecker, et al., 1994). Marginson and McAulay (2007) identified four sources of short-termism: changing market situations, transparent performance measurement of managers, individual dimension, and the organizational dimension.

Pressure from investors and the capital market especially after changes in market situation seems to induce managerial short-termism (Miettinen & Stenbacka, 2018). An extreme kind of short-termism can be survival or fire-fighting (Graafland, 2016; Marginson & McAulay, 2007) due to risks of running out of resources. In addition, executives of listed companies are pressured to provide performance in order to meet stock market expectations (Marginson & McAulay, 2007).

Transparent performance measurement drives managers to take actions that are solely based on maximizing short-term results, that will affect their performance within the current budgeting period (Laverty, 1996; Marginson & McAulay, 2007). Due to their own interests, managers are more likely to undervalue the long-term decisions when they are confronted with tradeoffs between the long term and the short term (Laverty, 1996).

The individual dimension regards an information deficiency. It describes the length of the time horizon confronting a decision maker and the information available. The greater the uncertainty, and the more likely information is deficient, managers tend to make short-term decisions accepting the risk of incomplete information available (Marginson & McAulay, 2007).

Organizational dimension describes considerable interpersonal communication, social interaction and social influence, which leads to possible short-termism (Laverty, 1996). Social influence perspective suggests that information from social referents (e.g., colleagues, coworkers, influential outsiders) can be at least as important as objective information, leading to conformity of views. In other words, an individual’s views and opinions can be biased by the opinions of others (Marginson & McAulay, 2007).

**Asymmetric cost behavior and short-termism in the context of quality costs**

Research in the field of asymmetric cost behavior and short-termism is mainly focusing on changes in sales and costs in general. In this paper, we transfer the idea of asymmetric cost behavior and short-termism into the context of quality costs. Well know sources gathered out of the literature review where designed into the system dynamics model.

Based on the model of Weiss, cost stickiness as phenomenon of asymmetric cost behavior of quality costs can be identified as:

$$\text{(2) } \text{STICKY}_{i,t} = - \left\lfloor \log \left( \frac{\Delta F_p}{\Delta F_c} \right)_{i,\tau} - \log \left( \frac{\Delta F_p}{\Delta F_c} \right)_{i,\bar{\tau}} \right\rfloor \quad \text{with } \tau, \bar{\tau} \in \{t, ..., t - 3\},$$

Using $Fp$ as failure prevention costs and $Fc$ as failure costs.
To transfer short-termism into the context of quality costs all four sources of short-termism of Marginson and McAulay (2007) can be applied because quality costs are directly affecting a company’s result (Jochem, 2014, p. 32). Quality performance of competitor, performance measurement by using quality-controlling figures as well as individual and organizational dimensions in the context to quality costs are providing relevance for manager’s behavior.

**System Dynamic Model**
Simulation can be defined as the practice of creating models representing existing or future systems with the purpose to experimenting in order to explain system behavior (Stadnicka & Litwin, 2019). System dynamics as a specific type of simulation that allows simulating a broad range of issues in dynamic systems (Sterman, 2010, pp. 41-42). Such models consist of interconnected stocks and flows that express the state of a system at a given time (Sterman, 2010, p. 68). The principles of system dynamics modelling, together with manufacturing issues, are widely presented in the literature (Größler et al., 2008). Sterman (2010) provides steps of the modeling process as well as examples which have been applied during the design of our model (Sterman, 2010, p. 86).

In this paper, we avoid describing the modelling process in detail but refer to a couple of Sterman’s models, which provided elements of our model. The model (figure 3) is in an early phase and some areas have been designed in a basic way to reduce complexity in the first step. The model includes three main areas: employees involved, parts moving in production, and financials.

![System dynamics model of quality costs](image)

**Figure 3: System dynamics model of quality costs**

Failure prevention costs are mainly defined by the sum of cost for QM-system, Q-planning, planned checking and testing and supplier management. The number of employees and their salary mainly defines all these elements. The area parts moving is designed by a basic stock and flow map for a basic manufacturing process (Sterman, 2010, p. 214), an inbound section (Sterman, 2010, p. 731) and delays (Sterman, 2010, p. 419).
The feedback loops for rework, scrap, claims and good will multiplied with the amount of parts in this loop are providing the failure costs. The area financials connects all types of quality costs with the financial result of the company. Another important function is the decision-making variable. Decision are the policies and protocols specifying how the decision maker processes available information (Sterman, 2010, p. 514). The rules of these decisions have been defined by the managerial behavior gathered out of the literature review, for example, asymmetric cost behavior in regard to failure prevention costs over four quarters even though failure costs are decreasing significant.

The model is still work in progress. This basic version is able to create oscillation of costs of quality triggered by managerial behavior. In an iterative process, more details and more parameters will expand the model to test different scenarios.

**Findings and conclusion**

The assumption of quality cost oscillation due to managerial behavior such as asymmetric cost behavior and short-termism can be confirmed with the help of our system dynamics model. The model cannot approve a long-term increase of quality costs so far. Due to the early state of our model, the identification of main sources of the oscillation is not finished yet. We also assume that the amplitude of oscillation and the increase of quality costs is limited by organizational factors (e.g. available budget, turnover or companies result). More details in the model in the area of decision-making and further research is necessary.

Abstract

Supply chain disruptions (SCDs) remain one of the most significant threats to firms’ performance. In this study we investigate chief executive officer (CEO) stock options as an antecedent of SCDs. Based on an eleven-year sample of more than 2,000 disruptions in U.S. S&P 500 firms we conceptually and empirically explain an inverted U-shaped relationship between CEO stock options and SCDs. We contribute to research the investigation of a previously neglected antecedent of SCDs, a more nuanced view on the strategic impact of CEO stock options, and insights on the moderating effect of relative chief operating officer (COO) power.

Keywords: Supply chain disruptions, CEO stock options, COO power

Full Paper

Introduction

Business interruption risks remain a significant threat to firms’ performance. Despite the high importance of SCDs for academia and practice, their causes are neither conclusively identified nor empirically well understood. Moreover, even though their decisions directly influence the supply chain, the impact of decision makers in charge of operations management is also neglected in operations management research (Hendricks, Hora, & Singhal, 2014). In this context, stock options are supposed to evoke more aggressive risk-taking by otherwise rather risk-averse executives in alignment with the shareholders’ interests. The concept of stock options allows executives to participate from the potential upsides of high-risk decisions with limited downside risks due to their optionality. This also comprises an increased willingness to take risks with regards to supply chain
management. Recent studies are ambiguous regarding the effectiveness of CEO options and call for further research on contingency factors impacting managerial risk taking (Benischke et al., 2019; Wowak, et al., 2015).

By contrasting agency and behavioral agency theory, we investigate the impact of CEO options on SCDs and the moderating effects of relative COO power and market uncertainty (see figure 1). We draw upon a unique, hand-collected sample of more than 2,100 firm-year observations over the years 2006 to 2016 with more than 2,000 SCDs in 223 S&P 500 firms. To support our manual sampling process, we used a machine learning algorithm to identify potentially relevant SCDs from more than 450,000 press announcements.

![Figure 1 – Simplified research model](image)

Our study contributes to operations management research in multiple ways. First, we identify and empirically investigate CEO options as a widely neglected organizational antecedent of SCDs. Second, we establish an inverted U-shaped relation between CEO options and SCDs enhancing research on CEO options with a more nuanced perspective on the effects of CEO options. Third, our study highlights the importance of having a powerful COO in the top management team with regards to supply chain stability. Fourth, we emphasize the necessity of adopting a contingency perspective when assessing CEO options and SCD risks. Finally, we introduce machine learning as a supporting technique to empirical secondary data research in operations management.

**Theoretical background**

**SCDs**

Prevailing research on SCDs emphasizes their harmful consequences: Hendricks & Singhal in several studies found, that SCDs diminish stock returns, market and shareholder value, and reduce sales over several years following a disruption (1997, 2003, 2005). In line with Hendricks & Singhal (2003) we define SCDs as unexpected events in the supply chain or its environment that threaten the normal business operations of a firm. Existing studies on SCDs vary strongly in the events being considered. Based on related supply chain risk literature, we use a dichotomous classification to cluster the SCDs used in our study. First, we separate micro- and macro-SCD-risks being in- and external to the organization (Wu et al., 2006). As we in this study investigate the effects of CEO stock options on SCDs, we exclusively focus on micro-disruptions which can directly be influenced by the firms. Loosely following the meta-analysis by Ho et al. (2015), we consider the following micro-disruptions in our study: demand and supply mismatches, delays, outages (of machinery or production), strikes, product quality issues, recalls, infrastructural problems, and issues of adverse business conduct. In line with Hendricks...
Singhal’s understanding of supply chain management and its subsystems, we assume that executives either indirectly (through negligence of important operations processes) or directly (through active strategic decisions or conscious misconduct) effect SCDs (2014).

(Behavioral) Agency Theory and CEO Options

The basis of agency theory and research on CEO options is the separation of ownership and management in firms, leading to potentially diverging interests between shareholders (principals) and managers (agents) (Jensen & Meckling, 1976). Principals delegate the management of the business to the agent (i.e. the CEO), who is assumed to act in their best interest. In this context, agency theory assumes, that agents are risk-averse. Stock options are supposed to reduce the CEOs’ risk-aversion by offering the CEO the opportunity to profit from firm success while not suffering from potential loss (Wiseman & Gomez-Mejia, 1998). Since CEO options are meant to influence a CEO’s behavior, behavioral agency theorists pronounce the need to combine agency with behavioral decision theory to fully explain its effects (Martin et al., 2016). Behavioral agency theory enhances agency theory by prospect theory to explain managerial risk-taking (Wiseman & Gomez-Mejia, 1998). Prospect theory postulates that managerial decision behavior depends on individual valuation of potential gains and losses to the personal wealth (Kahneman & Tversky, 1979) with wealth being understood as current, just-received, and fully anticipated wealth. Accordingly, agents weigh anticipated future wealth against declines in current endowed wealth (Benischke et al., 2019).

Development of hypotheses

CEO options and SCDs

If not in charge of operations themselves, CEOs have a strong impact on strategic decision-making regarding initiatives that affect company operations, such as cost-reduction programs, process-oriented programs (e.g. quality management, working capital management), or budgeting (e.g. R&D spending) (Wowak et al., 2015). Overly risky decisions in pursuit of stock performance optimization, thus, have the potential to evoke SCDs. Whereas agency theorists postulate a linear relation between CEO options and managerial risk-taking, based on the behavioral agency theory we assume that the relation between stock options and risk-taking is more nuanced and driven by two latent interacting forces: the perceived benefits in case of success and the perceived costs in case of loss associated with higher risk-taking by the CEO. CEOs with a low stock option share have little incentive to take risky decisions, as they only limitedly benefit from increasing share prices if the high-risk initiative achieves anticipated results. However, they have much to lose in terms of non-financial wealth or imminent penalties. With an increasing but still moderate CEO option share, the financial incentive to take risks increases, as the fully anticipated wealth assigned to high-risk initiatives becomes more compelling. As risk-taking preferences of an agent vary depending on the executives’ framing of the situation and anticipated effects on the personal wealth (Sitkin & Weingart, 1995), the CEO will constantly weigh benefits and costs of risky decisions against his current endowed wealth. Up to a certain point depending on the personal risk-taking preference, the incremental benefits of taking additional risks will overweigh the perceived incremental costs and will cause CEOs to ignore indications of project failure, to be negligent about risk mitigation, or to ignore downside risks of their decision (Wowak et al., 2015). As a consequence, we assume SCDs to increase. Following our logic of decreasing marginal benefits and increasing marginal cost of taking high-risk
decisions, we argue that with a high option share relative to the CEOs total compensation, risk-taking decreases as the CEO considers a large part of his prospect wealth at risk.

**Hypothesis 1 (H1):** CEO options exhibit an inverted U-shaped relationship to the frequency of SCDs, such that firms with low and high CEO option shares will experience fewer SCDs than those with medium CEO option shares

**CEO options, market uncertainty, SCDs**

When analyzing managerial risk-taking behavior, market uncertainty being defined as the extent to which a CEO faces an unpredictable and unstable environment (Finkelstein & Boyd, 1998) is arguably of special interest. Uncertain markets are characterized by constant variations in customers, preferences, and competition and increased supply chain risks per se (Trkman & McCormack, 2009). This will enhance the perceived costs of additional risk-taking by the CEO. Moreover, research suggests that with increasing market uncertainty firms face higher complexity in their task environment and an increased need to review and adjust strategies continuously (Miller & Friesen, 1983). This increases the alignment efforts within the top management team (TMT), which restricts the CEO in making high-risk decisions. Finally, with less predictability of the market and a growing amount of personal wealth being linked to firm performance, CEOs tend to become increasingly risk-averse and seek to preserve personal wealth (Wiseman & Gomez-Mejia, 1998). As the marginal costs increase as compared to the marginal benefit related to additional risk-taking, the U-shaped relationship between CEO options and SCDs is flattened, thus SCDs decrease.

**Hypothesis 2 (H2):** The inverted U-shaped relationship between CEO options and SCDs is (a) flatter in markets where uncertainty is high and (b) steeper in markets where uncertainty is low.

**CEO options, relative COO power, SCDs**

Past research suggests that the increasing marginal cost curve counteracting the marginal benefits of CEO options might increase in the presence of a powerful COO. Power is defined as the extent to which the COO can influence the behavior of others and has the discretion to shape and implement strategic decisions in his interest (Finkelstein, 1992). The COO frequently is delegated responsibilities usually held by the CEO. He, thus, reduces power distance in the TMT and constrains the power otherwise centralized in the position of the CEO (Worrel et al., 1997). With increasing power of the COO, the CEO needs to more closely involve him when initiating strategic changes in a firm’s operations. By creating a task-oriented conflict between CEO and COO, decisions are made in a process of social interactions that reveals differing assumptions and expectations (Marcel, 2009). This alignment process will arguably constrain the CEO’s tendency to disproportionally focus on upside potential of high-risk decisions with regards to operations and, in turn, increase the CEOs perceived risk to be blamed with a negative outcome of a high-risk initiative if pursued against opposition. Second, power structures in TMTs can create conflicts among executives. By contending the power of the CEO, the COO takes a monitoring role towards the CEO. This is based on an inherent competition between the CEO and COO and the fact that a weak performance of the operations function being visible to the external labor market might harm future employment opportunities of the COO (Fama, 1980). Third, the functional backgrounds represented in the TMT influence the salience of certain organizational objectives and performance drivers (Marcel, 2009). While Hayward & Hambrick show that CEOs – a
role rather focused on output-oriented than internal processes – tend to be more risk-seeking with higher individual power (1997), COOs will presumably act in the foremost interest of their functional responsibility and, thus, will challenge overly risky decision based on a profound understanding of the operations function.

Hypothesis 3 (H3): The inverted U-shaped relationship between CEO options and SCDs is (a) flatter, when the relative power of the COO is high and (b) steeper, when the relative power of the COO is low.

Data and methods

Sample
To empirically test our hypotheses, we gathered more than 2,000 SCDs from PR Newswire press announcements in the Factiva database from 223 publicly traded S&P 500 firms in the U.S. between 2006-2016. Based on the taxonomy developed above, we identified key search terms to identify first relevant disruption announcements per category, following the procedure of Hendricks & Singhal (2005). To handle the number of announcements and support our manual coding process, we developed a supervised machine learning algorithm, using python 3.6 & scikit-learn libraries, to automatically identify potentially relevant announcements based on both, title and body of the announcements. We re-read all announcements tagged as potentially relevant by the algorithm to judge the appropriateness, discussed unambiguous announcements. We, then, clustered the announcement into the SCD categories introduced above, using triple coding technique and regularly testing for intercoder reliability (Daniel & Harland, 2018). We then merged this SCD sample with TMT data from S&P Capital IQ’s ExecuComp and firm characteristics from S&P Capital IQ’s Compustat.

Measures
We operationalized our dependent variable (DV) supply chain disruptions as count variable (i.e. the number of recalls of firm i in year t), ranging from 0 to 8 in our sample. Our independent variable (IV) CEO options was operationalized as the share of stock options granted relative to the total compensation of the CEO as reported by ExecuComp. Following prior research, we calculated this variable as a two-year weighted average (Wowak et al., 2015).

With regards to our moderating variables, we put our focus on the presence of the COO role rather than on the title as such, following Hambrick & Canella (2004). We operationalized COO relative power as the COO’s total compensation relative to the total compensation of the highest paid TMT member (the CEO). This definition implies that higher relative compensation ratios indicate higher power in the TMT (Daily & Johnson, 1997). We operationalized market uncertainty as the coefficient of variation of sales per industry on four-digit SIC code level in a given year (Tosi et al., 1973).

To increase robustness of our research model we included multiple control variables on firm-, industry- and TMT-level. On firm-level, we controlled for firm size, financial slack, operating performance, past financial performance using Tobin’s Q, R&D intensity, and capital intensity. On environmental-level, we controlled for market uncertainty, technological turbulence, and technological sophistication. On TMT-level we considered TMT size, TMT ownership structure, CEO duality, and COO relative power. Since firms with a history of SCDs may be more likely to subsequently encounter problems, we included lagged DVs in all models. Finally, all research models contain year and industry dummies. We lagged all variables in our model (except for the DV) by
one year to account for the fact, that strategic decisions based on information in a given year, will take time to become effective (Souder & Bromley, 2012). All continuous variables are winsorized at the 1.0% level to avoid bias from outliers.

**Model**

We use STATA’s generalized estimating equation (GEE) model to analyze our unbalanced and pooled cross-sectional time-series data, following structurally similar studies based on longitudinal data (Wowak et al., 2015). GEE measures the effect on the DV “population-averaged” across all units in the data set, thus, considering both, within- and between-unit variation. Unlike alternative approaches (e.g. random- or fixed-effect models), GEE can deal with potential heteroscedasticity and serial correlation as it accounts for both inter- and intra-firm variations (Shah et al., 2016). Moreover, GEE does not (wrongfully) omit “zero SCD” firms (Sine et al., 2003).

**Results**

Table 1 provides descriptive statistics (unstandardized) and correlations (standardized) for all variables used in our models. The top right part of the matrix shows Spearman’s rank-order correlations, the bottom left values show Pearson’s product-moment correlations. The fact there is no significant correlation between CEO options and SCDs might be a first indication that the relationship might indeed not be linear rather curvilinear / U-shaped.

As we have COO presence in only 53.6% of all firm-year observations we shrink our sample size by 990 observations with the inclusion of the COO power moderator and control variable. Accordingly, we tested hypotheses 1 and 2 ex ante in separate models without the COO power variables. We repeated the tests in a second group of models including the COO power moderator and variables to test hypothesis 3. This approach allowed us to test hypotheses 1 and 2 without a potential COO presence selection bias.
Hypothesis 1 theorized an inverted U-shaped relationship between CEO options and supply chain disruptions. Necessary condition for such a curvilinear relationship is a negative second-order effect of the IV in our regression model. In support of Hypothesis 1, model 1-2 shows that CEO options have a highly significant effect on supply chain disruptions and the second-order effect is significantly negative. In hypotheses 2 and 3 we theorized a flattening in the inverted U-shaped relationship between CEO options and supply chain disruptions by our interaction effects. A flattening (or steeping) of a quadratic relationship requires the regression coefficient between the interaction effect and the squared IV to be significant and positive (negative) (Haans et al., 2016). As depicted in our full model 2-5 the coefficients of both interaction terms are significant and negative, with their corresponding second-order effects being significantly positive. H1, H2, and H3, thus, are strongly supported.

negative binominal distribution best fitting our count data DV. To ensure our results are not driven by model specifications, we reran the analysis with an ordinary least square (OLS) random effects model with robust standard errors (model 3-1) and with Driscoll-Kraay standard errors to rule out cross-sectional correlation (model 3-2) (Shah et al., 2016). Both models confirm the results presented above. Next, we reran our main model with two different specifications of our IV using an unweighted average in model 3-3 and annual values in model 3-4. Again, our estimations are confirmed.

Firms with COOs might be substantially different from firms without COOs. Unobserved factors (e.g. operations management experience of the CEO) might influence both, the decision to have a COO and supply chain related outcomes and bias the results of our study. To test for this potential sample selection bias, we applied a Heckman two-stage selection model (1979) in line with prior TMT research (Kim et al., 2016) and included an inverse Mills ratio (IMR) predicting COO presence in all our models 2-1 to 2-5. As the IMR is insignificant and all other results remain robust, our analysis does not suffer from a sample selection bias. The results including the IMR are shown for the full model in model 3-5. Moreover, we drew on multiple means to lower the risk of potential endogeneity in our study. Among other measures, we created an endogeneity control by regressing CEO options in $t - 1$ on eleven of its potential firm-, industry-, and TMT-level antecedents in $t - 2$ and including this predicted IV as endogeneity controls in our models 2-1 to 2-5. Again, the results remained robust in all models. We show the results for the full model in model 3-6. Given the results of the tests above, reverse causality and endogeneity do not appear to be a problem in our study.

**Discussion**

**Theoretical Implications**

Our findings have important implications for research on SCDs and the extensive literature on the impact of CEO options on executive behavior. First, we extend operations management research by investigating CEO options as an organizational antecedent of SCDs. We empirically show, that CEO options – especially at medium levels – increase the frequency of SCDs. Second, we contribute to strategic management research which investigates the effects of executive stock options. While research on this topic has long been dominated by two schools of thought – agency theory expecting more risky decisions and behavioral agency theory expecting less risky decision as consequences of stock options – our research conceptually and empirically adds a more nuanced assessment of CEO options to prevailing literature. Third, this study identifies both organizational and environmental factors that have significant impact on CEO option-induced risk-taking. Both, market uncertainty and relative COO power have a flattening effect on the relationship between CEO options and SCDs, thus, diminishing the CEOs willingness to take disproportionate risks with regards to operations management. As of today, research on performance effects of COOs is ambiguous (Hambrick & Cannella, 2004; Hendricks et al., 2014). Our findings underline the importance of a COO at equal terms with regards to supply chain stability and further confirms research underlining the importance of operations capabilities in the TMT as a source of competitive advantage.

Finally, our study advances strategic and operations management research from a methodological standpoint. As the algorithm is not limited to a predefined dictionary of relevant terms but constantly evolves based on the growing training data set, this approach might be an interesting alternative to dictionary-based approaches. Especially in times of “big data” that can hardly be managed manually anymore and for relatively new areas of research where no established dictionaries exist, this approach can become increasingly relevant.
Practical Implications
Our findings bring about two important implications for decision makers. First, we advise decision makers to carefully select and combine different tools of executive compensation. Whereas CEO options might not be the best incentive used by itself, they still might be a valuable tool to induce additional risk-taking if required. However, this decision needs to be made very deliberately, keeping in mind potential risks. We, thus, recommend decision makers to balance CEO options with other means of executive compensation such as stock that also have a downside potential and reward sustainable decision making. Second, if using CEO options, we advise decision makers to embed their usage in an organizational setting that either does not facilitate strategic individual actions by the CEO or, as this study has proven, has a relatively low power distance in its TMT to enable mutual control among executives.

Limitations and Avenues for Further Research
Our study is subject to certain limitations that provide interesting avenues for further research. First, while our study focuses on the effects of CEO options, future research should investigate the interplay of CEO options with other prevailing means of executive compensation (e.g. stock ownership) in predicting supply chain stability. Second, whereas we focused on CEO compensation, it might be of interest to investigate effects of additional TMT characteristics on supply chain stability. Third, research has a strong focus on the CEO when investigating the effects of stock options. Future studies could expand this scope to other TMT members’ roles and strategic outcomes in their areas of responsibility to better understand potentially diverging interests between different functional strategies.

Abstract

Building on the social exchange perspective and organizational support theory, this study aims to evaluate the relationship between truck driver’s procedural and interactional justice perceptions and their affective commitment to their employers. We set out a Transactional Justice Interaction Reference Model and refine it by scientific testing. The evidence is based on survey data collected at a truck-driving school near Frankfurt, Germany, providing update and safety classes to long-standing truck drivers in logistics and SCM. The results are derived by using structural equation modelling and indicate that perceived organizational support plays a mediating positive effect on developing organizational commitment.

Keywords: organizational justice in employer-employee relationships, truck drivers' perceived organizational support, relational contract in transportation industry

Introduction

Since 2010, the demand for freight transport in German road haulage has been rising steadily. Nevertheless, due to an acute driver shortage, German haulage companies and freight carriers often cannot profit from the constant growth of the German transport sector due to an acute lack of prospective job applicants (Schierge, 2014). At the same time, the phenomenon of occupational driver shortage is strongly interwoven with increasing changes in employment relations, leading to the assessment that one of the most serious entrepreneur risk for German carriers is high driver fluctuation (Peirowfeiz and Large, 2013). Additionally, the German transport industry is currently not only facing a shortage in drivers but also a competition over the quality of B2B services, of which
truck drivers, due to their boundary-spanning role, are an important part (Peirowfeiz and Large, 2013).

Employee commitment, also known as the relational contract, is known to bear beneficial characteristics for operational success. This is more so for customer-facing, boundary-spanning roles such as truck drivers. To address a gap in knowledge in the transport and logistics industry, our paper presents a quantitative assessment of employee satisfaction in German transport organizations.

Recognizing the desirability of employee commitment in their role for ensuring competitive advantage, the focus of this study shifts from remuneration (establishing merit-based distributive justice) towards information policy and treatment. The procedural and interactional qualities or justice are tested as to their significance for dedicated in-role behaviour. More specifically this research aims to answer the following questions:

RQ1: To which extent do procedural and interactional justice in organizations positively affect truck drivers’ experience of being managed?

RQ2: By which justice-induced interaction mechanism is truck drivers’ dedication towards their workplace significantly improved?

Based on a recent, personally administered, survey among 62 truck drivers of various employers, a structural employee commitment model based on an extensive literature review was tested. Our research is aiming at depicting potential improvements as to truck driver retention in times of employee scarcity by means of transparency, communication and courteous treatment. The subsequent sections will first provide an account on the extant literature in the field, followed by the methodological setup and the research procedures. After the discussion of the scientific results, a brief conclusion and managerial implication will be provided.

**Literature Review**

The driver shortage problem is not new and is also acute not only in more developed countries (Rauwald and Schmidt, 2012; Sheffi, 2015) but also in emerging countries e.g. India (Dash, 2011) or Brazil (Anon., 2014). For this reason, there has been a lot of research conducted in many countries but mostly in the US, Canada, Australia, UK, France and to a certain extent in Germany. The results of this research suggest that shortage is the result of numerous and often inter-related factors.

Some of the reasons behind driver shortage are specific to individual countries. Scholars have found increased regulation, such as in the US (Morris, 2015) or in the EU, especially in Germany (Ball, 2011) to be an impediment for employee recruitment and retention. The age structure of the truck drivers in a specific population (Soergel, 2015) varies among countries, as do infrastructural conditions e.g. the lack of parking space along highways like in Germany (Peirowfeiz and Large, 2013). Scholars have also found that general higher qualification standards and requirements may crowd out the potential for recruits in the transportation sector, as observed e.g. in the EU member states and particularly in Germany (McKinnon et al., 2017). The lack of personnel is however also founded in ubiquitous attributes, low wage rates making the occupation relatively unattractive anywhere in the world (Sheffi, 2015).

To this add truck drivers’ temporal and ergonomic working conditions that cause emotional exhaustion (Kemp, Kopp and Kemp, 2013) and physical strain (Robb and
Mansfield, 2007). Scholars have found the truck drivers' profession to maintain a poor public image and to undergo constant socio-technological changes, particularly due to increasingly refined driving performance monitoring by on-board devices (European Parliament, 2009; Adell, 2010; Ghazizadeh et al., 2017). Finally, extant research lists employer-related phenomena as world-wide impediments to recruiting truck drivers, namely perceived organisational injustice (Cantor, Macdonald and Crum, 2011) and the lack of organisational support (Fournier, Lamontagne and Gagnon, 2012; Kemp, Kopp and Kemp, 2013).

Despite the severe impact on business operations, comparatively few studies in the German research are addressing these generic factors contributing to truck driver shortage. Investigations carried out in Germany to date focus mainly on the difficult working conditions, such as long and irregular hours or, in the case of long-distance trucking, long absence hours from home (Large, Breitling and Kramer, 2014). Furthermore, amounts of earnings/remuneration (Peirowfeiz and Large, 2013) and, in places, the time and performance pressure perceived by professional drivers (Roth et al., 2004) have been discussed as a cause for driver shortage. Apart from this, the aspect of the lack of organisational support is acknowledged by Large et al. (2014). The authors carried out an investigation among professional truck drivers in German-speaking regions and inquired about emotional variables, such as perceived organizational support and affective commitment.

However, the German literature exhibits a remarkable absence of an explicit discussion of organisational justice in the context of professional drivers. Nonetheless, surveys on operational practice show that truck-driving personnel tend to churn on the basis of workplace-related interactions perceived as unfair (Gaida, 2008; Peirowfeiz and Large, 2013).

**Transactional Justice Interaction Reference Model**

*Types of justice*

This study is based on the assumption that the concept of organisational justice denotes a multi-factorial structure. Next to distributive justice, which is not being included in this work, procedural and interactional aspects play a crucial role in theory and professional practice (Cropanzano and Ambrose, 2015). This arises from the consideration that, in addition to the perception of fairness of formal structures and processes, employees of an organisation also pay attention to how they are dealt with during the execution of determined processes (Greenberg, 1993).

*Procedural justice (PJ)* refers to the procedure for decision-making processes. Decisive for the perception of fairness is whether the persons affected can have an influence on the procedure and the result. Moreover, consistent adherence to rules and ethical standards as unbiased managerial decisions bear further relevance (Thibaut and Walker, 1975; Leventhal, 1980).

In addition, interactional aspects of fairness assessment include two more significant aspects as follows:

1. Interpersonal justice refers to the perception of the social interaction in the context of the decision-making process and hints toward the degree of courtesy, dignity and respect a person is treated with (Bies and Moag, 1986; Greenberg, 1993).

2. Informational justice refers to whether the informative behaviour of decision-making persons is honest, whether justifications and relevant information is being included, and whether the information is being given in a timely manner (Bies and Moag,
1986; Greenberg, 1993; Shapiro, Buttner and Barry, 1994). In the present study, these two aspects are measured on company level which is why a high correlation can be expected (Ambrose and Schminke, 2003). Therefore, both will be considered as one dimension named perceived interactional justice (IJ).

According to the agent-system model of organisational justice (Tyler and Bies, 1990) procedural justice perceptions should be associated with organizationally directed outcomes as procedures may be viewed as institutionalized while interactional justice is commonly associated with organizational agents (supervisors) enacting the procedures (Bies and Moag, 1986). Nevertheless, Colquitt et al. (2001) point out that employees may not exclusively link interactional fairness to supervisors and procedural fairness to organizations. A multi-focal perspective asserts that perceptions of unfairness can be attributed to a number of different sources (Byrne, 1999; Rupp and Cropanzano, 2002).

Perceived organizational support (POS) and affective commitment to the organization (ACO)

For the purpose of this study and based on the organisational support theory, it is assumed that individually perceived organizational justice has a close correlation to the development of feelings and beliefs (Rhoades and Eisenberger, 2002). Professional truck drivers who are convinced that their organization treats them fairly and demonstrate circumspection as to the drivers' quotidian necessities are reaffirmed that their well-being is being sought and their efforts appreciated by their organisation.

According to the social exchange theory, this POS support evokes a sense of conscientiousness and organisation in-role identification, commanding a particularly positive effect on the reciprocal relationship between employee and organization (Eisenberger et al., 1986). Overall, it can be assumed that the POS mediates between processes or the perception of organisational justice and the individual attitudes of an employee towards the organization (Allen, Shore and Griffeth, 2003).

Particular relevance for this context is attributed to the phenomenon of the ACO which describes the degree of socio-psychological connection to an organisation (Rhoades, Eisenberger and Armeli, 2001), bearing significance for an employee's continuance intentions (Gautam, Van Dick and Wagner, 2004). Accordingly, a number of studies show a positive correlation between lack of affective commitment and the intention to quit (Meyer et al., 2002). This leads to this study's claim that procedural and interactional justice – each in their own right – generate positive perceptions of being supported by the organization. This well-being we claim to foster affective commitment towards the workplace. In our claim, POS thus serves as a mediating variable between procedural and interactional justice on the one hand and affective commitment in an organization on the other.

Hypotheses

The above discussions lead to the Transactional Justice Interaction Reference Model's following hypotheses:

H1: Perceived organizational support mediates the effect of perceived organizational procedural justice on truck driver’s affective commitment.

H2: Perceived organizational support mediates the effect of perceived organizational interactional justice on truck driver’s affective commitment.
The research model is presented in Figure 1.

![Figure 1: Research framework](image)

**Figure 1:** Research framework

**Methods**

**Instruments**

Maintaining an interpretive philosophical stance, the methodology was based on quantitative questionnaires asking for respondents’ perceptions on a measured scale. A reflective measurement model based on Greenberg (1993), Byrne (1999), Cropa et al. (2001) and (Müller, Kärcher and Kals, 2011) is developed, holistically representing organizational perception as experienced by truck drivers in their respective company. The underlying factor structure is validated by a confirmatory factor analysis.

The measurement of the POS is operationalized by select qualities set out by Eisenberger et al. (1986). Affective Commitment is elucidated by standardized subjects described by Felfe et al. (2014). All dimensions are tested on a 5-point Likert scale. The applicability of all measurement scales is verified in a pretest with twelve respondents and adjusted accordingly. Control variables are set out as age, duration of organizational employment and qualification.

**Sampling**

As this study is about employee retention, the stabilized perception of highly desirable long-standing truck drivers is particularly relevant. 62 professional drivers were surveyed using a standardised questionnaire. The research was carried out in close cooperation with a truck-driving school near Frankfurt, Germany, providing update and safety classes to long-standing truck drivers of various logistics and supply chain companies. Therefore, the sampling consisted of safety-aware, skill-oriented drivers with a retention of at least three years in their profession. The questionnaires were distributed on-site and re-collected the same day, ensuring a high response rate. The results were administered to AMOS24 for covariant factor analysis and reliability testing.

**Measurement criteria**

In this section the fit between the theoretical model and the data was assessed. Five usual goodness-of-fit indices were used to assess overall model fit, namely Bentler's (1989) comparative fit index (CFI), Bentler and Bonett's (1980) non-normed fit index (NNFI), Trucker-Lewis index (TLI), discrepancy divided by degree of freedom (CMIN/df) and root mean square error of approximation (RMSEA) (Steiger, 1990) and due to the small sample the standardized root mean square residual (SRMR) as suggested by Byrne...
(2016). Values higher than the 0.90 cut-off for the CFI and TLI, and a value lower than 0.08 for the RMSEA suggest an appropriate fit between the model and the data (Browne and Cudeck, 1993; Baumgartner and Homburg, 1996) while a value under 0.6 for the SRMR is appreciated in a well-fitting model (Byrne, 2016).

For scale reliability, the Cronbach’s alpha was measured and a cut-off value of 0.7 was considered as suggested by (Garver and Mentzer, 1999).

**Data analysis**

*Measurement model*

A confirmatory factor analyses was conducted for the constructs in order to assess one-dimensionality, validity, and reliability of the theoretical model. On the basis of the analysis and sample size, the model shows acceptable fit with the data: CFI = 0.953, TLI = 0.941, RMSEA = 0.082, SRMR = 0.060. The minimum sample discrepancy (CMIN/df = 1.414) was below the cut-off 3-0 (Simon and Paper, 2007).

The corresponding measures for scale reliability were: PJ (four items; 0.922), IJ (five items, 0.919), POS (three items; 0.853) and AOC (three items, 0.831).

*Structural Model*

Our statistical result showed the following degrees of significance among justice-induced qualities in truck drivers' workplace-interactions as in figure 2. On the basis of the analysis and sample size, the model shows also acceptable fit with the data: CFI = 0.924, TLI = 0.907, RMSEA = 0.099, SRMR = 0.062). The minimum sample discrepancy (CMIN/df = 1.650) was also below the cut-off.

![Diagram](image.png)

**Figure 2:** Statistical findings; Transactional Justice Interaction Reference Model
Discussion

Quantitative evidence on the Transactional Justice Interaction Reference Model as depicted in Figure 2 reveals that a direct relationship between procedural justice (PJ) and affective commitment (ACO) can not be established. However, perceived organizational support (POS) is fostered by procedural justice, while reinforcing affective commitment, thus acting as a mediator between the two qualities. This is in line with findings of Rhoades and Eisenberger (2002) who assert that the perceived organizational support will positively affect in-role dedication. It is also consistent with Bies and Moag (1986) as well as Tyler and Bies (1990) who link procedural justice perceptions to institutions. Our hypothesis \( H_1: \) **Perceived organizational support mediates the effect of perceived organizational procedural justice on truck driver’s affective commitment**, can thus be considered as verified.

However, as shown in Figure 2, there is a significant correlation between interactional justice (IJ) and affective commitment (ACO). The assumed moderating effect of perceived organizational support (POS) can not be established as it will not reinforce the direct influence of IJ and ACO. Notable scholars (Bies and Moag, 1986; Tyler and Bies, 1990) in fact link interactional justice with organizational agents rather than with the organization itself. It however contradicts the more general claims of Allen, Shore and Griffeth (2003) linking overall organizational justice to a dedicated attitude only if perceived organizational support can be established. Our hypothesis set out as \( H_2: \) **Perceived organizational support mediates the effect of perceived organizational interactional justice on truck driver’s affective commitment**, can thus not be verified in practice.

Our research questions stated initially can thus be answered as follows:

**RQ1:** To which extent do procedural and interactional justice in organizations positively affect truck drivers’ experience of being managed?
There is strong first evidence among experienced German truck drivers that procedural as well as interactional justice will have a significant impact of in-role satisfaction.

**RQ2:** By which justice-induced interaction mechanism is truck drivers’ dedication towards their workplace significantly improved?
Our studies in the German truck driving industries suggest that procedural justice will have a positive effect on perceived organizational support which in turn reinforces the truck drivers' affective commitment. Interactional justice will in turn directly foster affective commitment.

Managerial Implications

Our findings bear managerial implications in, but presumably not limited to, managing German truck drivers.

First, organizational procedures have to be aligned with the driving personnel's operational and socio-technological requirements in order to convey a perception of being supported within the organization. This will, according to our current findings, enable a more dedicated and conscientious in-role behaviour.
Second, managers in person have to constantly review their mode of information dissemination in the workforce and their behaviour in interaction with truck drivers. Apart from the situation in the company, this behaviour will directly influence the psychological contract their truck driving staff can develop.

**Limitations and further research**

Our findings contribute by identifying gaps between theory and practice against the background of non-distributive dimensions of justice, as well as the by developing a generic structural model for testing in-role commitment in the context of truck drivers.

Limitations of generalizability apply due to the regional focus in Germany, the particular industries as well as the current economic boom and the overall sample size, which is small compared to the large number of truck drivers in Germany. Another limitation is that all measures are based on respondents' situated perception, which are not only subject to interpretation but also to cultural and organisational understanding and may change over time. Finally, the habitat of truck driving schools may evoke particular responses that may have to be fortified in different settings in the future.

Finally, this research rises some managerial and academic questions for the future:

- How can drivers, despite their frequent physical absence from the workplace, be empowered as to obtaining the necessary and reassuring processual and informational transparency and support that makes them dedicated towards their role?
- Which socio-cultural and socio-technological factors are particularly capable of creating the strong perception of being treated in a courteous, fair, and amiable manner?
- Is there a corporate culture that particularly fosters such positive perceptions?
- These constituents of non-distributive justice will require further academic scrutiny as well as managerial attention.

Abstract

The interaction between employees and clients is a significant factor in reaching operational effectiveness, and one of the key aspects which define the result of human interaction is emotional intelligence. However, the extent to which emotional intelligence contributes to the acceptance of innovation and therefore the improvement of operational effectiveness, still needs to be explored. Based on data collected from 150 surveys, and using Structural Equation Modeling, this study found that there is no influence of emotional intelligence on the acceptance of the strategies but it has a strong impact on the linkages and operational effectiveness.

Keywords: Emotional Intelligence, Strategies, Linkages, Operational effectiveness

Introduction

In this globalized market, competitiveness is a vital factor for the survivability and improvement of performance (Porter, 1996). Central to competitiveness is the sustainability of the competitive potential and managing the competitive process and thus the operational effectiveness. Hence, the effectiveness of management and strategies in organizing the processes and activities plays a fundamental role in the alignment of this dimension (Buckley et al., 1988). The competitiveness of the firm is based on operational effectiveness and organizations dedicate significant amounts of time and resources to develop strategies to increase performance through operational effectiveness (Santa et al., 2017). Additionally, the interaction between employees and clients is a significant factor in applying innovation strategies aimed at reaching operational effectiveness, and one of the key aspects which define the result of human interaction is emotional intelligence (Birdi et al., 2008; Bowen et al., 1990).

The existing literature on emotional intelligence in Colombia is scarce and based mainly on the effects that emotional intelligence has on human behavior and human interaction related to leadership but not on innovation or the operational effectiveness of organizations (Acosta-Prado et al., 2015; Sadri et al., 2011; Zárate Torres and Matviuk, 2012). The fact that there is a need to explore the role of emotional intelligence in work outcomes (Wong and Law, 2002), and particularly in strategy and linkages, and its impact on operational effectiveness, together with
Goleman’s (1998) observation that emotional intelligence is related to job performance, motivates this study. Therefore, this exploratory endeavor seeks to investigate whether aspects of emotional intelligence impact on strategies, linkages, and operational effectiveness, based on quantitative data collected from organizations in Colombia.

**Emotional Intelligence**

The concept of emotional intelligence is based on the idea of social intelligence identified by Thorndike in 1920. Social intelligence is defined as the ability to understand individuals and act intelligently in human relations (Thorndike, 1920). Later on, Gardner (1993) included social intelligence into the framework of his theory of multiple intelligences and concluded that it is constituted by interpersonal and intrapersonal intelligence. The concept of intrapersonal intelligence comprises the ability to symbolize a set of different and complex feelings while the concept of interpersonal intelligence is the ability to identify, make distinctions, and notice the feelings of other individuals (Gardner, 1993). The judgement and introduction of emotional intelligence competencies started with research on talent and, initially, such competencies were considered to be abilities and part of the personality of every individual. (McClelland et al., 1958). Later, in the early seventies, research focused on these abilities and changed the label into competencies (McClelland, 1973). Hence, emotional intelligence cannot be considered as a part of an individual’s personality (Law et al., 2004). According to Boyatzis (1982), competencies are defined as any underlying characteristics of the individual that lead to superior performance. Therefore, emotional intelligence is a competency related to human behavior with goal of understanding people or gaining prestige by using empathy (Boyatzis, 2008).

Emotional intelligence recognizes and uses emotional information to gain influence over other individuals and obtain a superior personal or collective performance (Mayer and Geher, 1996). Initially, emotional intelligence was thought to comprise three mental processes: assessment and expression of one’s own emotions and those of others, regulation of one’s own and others’ emotions, and use of emotions (Mayer and Geher, 1996; Salovey and Grewal, 2005). Further refinement of the concept of emotional intelligence added a fourth dimension. Accordingly, the four key dimensions of emotional intelligence are now considered to be appraisal and expression of emotion in the self (SEA), appraisal and recognition of emotion in others (OEA), regulation of emotion in the self (ROE), and use of emotion to facilitate performance (UOE) (Mayer and Salovey, 1997; Salovey and Mayer, 1990; Wong and Law, 2002).

Appraisal and expression of emotion in the self: This concept relates to the ability of the individual to understand their own deep emotions and the ability to express them naturally (SEA).

Appraisal and recognition of emotion in others: This concept relates to the ability to perceive and understand the emotions of other individuals and react accordingly (OEA).

Regulation of emotion in the self: This concept relates to the ability to auto-regulate the own emotions (ROE).

Use of emotion to facilitate performance: This concept relates to the ability of individuals to use their own emotions to enhance personal and collective performance (UOE).

All four dimensions determine the creation of emotional linkages between different counterparts. However, this article will consider only SEA, which is defined as the ability of individuals to understand their deep emotions and to express these emotions naturally, and UOE, which is defined as the ability of individuals to make use of their emotions by directing them towards constructive activities and personal performance (Wong and Law, 2002).

**Linkages**

Linkages are the key element in human and organizational interaction. Both persons and organizations depend on linkages to improve organizational and personal performance and
generate operational effectiveness. Linkages facilitate the exchange of resources, capabilities, and knowledge and are vital in developing an effective strategy to increase firm performance. Linkages also are perceived to have a strong relationship with the quality of the service, the quality of the system, and performance, fundamental in operational effectiveness (Coo and Verma, 2002). Linkages play an important role in the strategic development of any organization. Without linkages, innovation is difficult to achieve. Innovation depends on how the companies are linked together. Linkage blocks can be complementary blocks made up of firms from different strategic groups with complementary capabilities or competencies, or pooling blocks composed of firms from the same strategic group. Any organization can be part of one, both, or none of the blocks (Nohria and Garcia-Pont, 1991; Roper and Love, 2018). In that context, Cassiman et al. (2010) maintains that firms that are using efficient linkages have superior innovation and organizational performance.

It has to be emphasized that organizations are made up of different persons, who interact internally and externally. Therefore, any linkages between organizations are based on personal linkages. Emotional intelligence is the key driver of behavior of any employee in any organization and plays an important role in the success of any person within an organization (Abraham, 1999; Carmeli, 2003). Linkages are closely related to emotional intelligence since human behavior facilitates or prevents linkages. Emotional intelligence improves leadership abilities and the interaction between members of different groups and organizations, facilitating the network relationship between them (Leban and Zulauf, 2004). Emotional intelligence is also a moderator to emotional and behavioral reactions with other people and defines how strategies of interaction and linkages are built up (Freshman and Rubino, 2004; Jordan et al., 2002; Lopes et al., 2004). This clearly supports a relationship between linkages, emotional intelligence, and organizational performance.

**Strategies**

Operational effectiveness (OE) is a primary competence of any organization in establishing processes that encourage organizations to exceed customer expectations (Santa et al., 2014). OE can also be crucial in defining the competitiveness of an organization. In that sense, organizations need to operate better and faster than their competitors, otherwise, they lose their competitive advantage (Tuturea and Rotaru, 2012). To achieve OE, organizations develop different strategies including defining long-term objectives, the methods to achieve them, and ensuring the necessary resources. How the goals will be achieved is not specified by the strategy. In this sense, planning and strategy are different concepts.

Strategies make the difference in each market for the firm (Hendela et al., 2017). As a consequence, the combination of operational efficiency and strategic flexibility is the imperative requirement for reaching peak performance (Boer et al., 2006; Johnson, 2006). Emotional intelligence facilitates the implementation of strategy in any organization. Today’s business requires reducing costs, increasing customer satisfaction, and enhancing firm performance. To reach these goals, organizations implement different strategies, such as changing processes, installing project management teams, or facilitating communication between different actors inside and outside the organization. Such strategies are implemented by different individuals and require a transformational leadership style. Emotional intelligence capabilities allow the leader to use his/her transformational power to foster the strategies defined by management and therefore reach organizational goals (Kilduff et al., 2010; Leban and Zulauf, 2004).

**Operational effectiveness**

Markets and environment change every day, and competition is fierce. To any organization trying to survive in the market such conditions are threats and affect their performance. Organizations answer the challenge by improving internal processes, making them more
efficient and therefore reducing operational costs (Belton, 2017; Helfat and Martin, 2014; Lin et al., 2016; Pisano, 2017; Prajogo et al., 2018; Teece et al., 1997). Two different generic strategies are employed to reach sustainable competitive advantage: Cost leadership and Differentiation (Dess and Davis, 1984; Huang et al., 2015; Porter, 2004). Clearly, OE is part of cost leadership strategy and, hence, a substantial driver of the organization’s performance. Undoubtedly, performance has significant impact on competitiveness. Therefore, an organization needs to focus on the dimensions of speed, flexibility, reliability, cost, and quality (Hill, 2005; Santa et al., 2014; Singh et al., 2018).

Porter defines OE as performing activities different and in a better way than the competitors. This definition includes efficiency, but it is not limited to it. Any activity that allows the firm to process its input in a more efficient or better way than their competitors can be judged as improving OE (Porter, 1996; Porter, 2013). Taturea & Rotaru (2012) make a distinction between strategy and OE, but highlight that both dimensions are necessary to improve performance and gain competitive advantage over competitors. Therefore, organizational success is based on OE, a core capability of any organization. OE allows the firm to act better and faster than their competitors and offer value-adding services or products, exceeding customers’ expectations (Namnai et al., 2015; Porter, 1996; Teece et al., 2016).

One of the key activities of the organization to enhance OE is the capability to measure, control and improve the processes. Any measure with the objective to eliminate waste, reduce costs, and use modern and efficient technologies will make better use of scarce resources (Porter, 1996). Difficulties arise when there are no valid or commonly accepted standards to measure performance. Uncertainty in measurement methodologies is more frequent within the service environment than in manufacturing sectors, since service industries are more prone to human interaction and measuring human interaction is more difficult (Phillips and Jeong, 2001). Another difficulty arises when benefits are not only quantitative, but also qualitative (Brigham and Ehrhardt, 2017; Ehrhardt and Brigham, 2015; Gomes et al., 2007; Gomes et al., 2008). Defining the primary and supporting activities of the firm at any point of the production/service process for both internal and external customers is an adequate start to solving the problem. As a second step, the organization can define how to add value at every point of the process or value chain, in accordance with their needs, objectives, and goals (Jansen et al., 2006; Najafi-Tavani et al., 2018; Rosenbusch et al., 2011).

The operational effectiveness dimension of speed refers to the answer time of the organization to adapt to changes in market condition and customers’ requirements. Constant market changes require fast answers from the organization, not only in delivering new products or services, but also in process changes (Phillips and Jeong, 2001; Tidd and Bessant, 2009).

Flexibility is a key factor in any organization and is considered a core capability, whether the firm offers services or products, or is a profit-orientated or a non-profit organization (Slack et al., 2006).

Cost performance consists in being more efficient and organizing and aligning processes to generate a minimum of waste in all organizational activities (Russell and Taylor, 2008). Cost performance considers the relationship between cost and reaching the organizational goals at the lowest price (Bisbe and Otley, 2004).

Quality has many aspects. Satisfying customers’ requirements and offering products they need is one facet. Zero defect production is another feature and impacts heavily on cost performance (Love et al., 1995). But quality also considers service methods, post-sale service, service facilities and location, service personnel, service consistency, response attitude, repair quality and any other characteristics that increase customer satisfaction (Yang, 2011).

**Research model and hypotheses**
From the perspective of work satisfaction, emotions become the mediator between emotional intelligence and commitment to the organization. Such commitment is reflected in better
behavior and performance. Therefore, a team member with a high level of emotional intelligence will have a significant impact on the team's effectiveness (Othman et al., 2008). Furthermore, a team leader with a high level of emotional intelligence recognizes emotions and is able to use this information to influence the team members (Amabile et al., 2005; George, 2000; Liu and Liu, 2013). Therefore, we propose the following hypotheses:

H1a: There is a direct impact of SEA on Linkages
H1b: There is a direct impact of SEA on Strategies
H1c: There is a direct impact of UOE on Linkages
H1d: There is a direct impact UOE on Strategies
H2a: There is a direct impact of SEA on OE
H2b: There is a direct impact of UOE on OE

Strategies define how to reach expected goals and are therefore vital to OE (Papke-Shields and Malhotra, 2001). Linkages facilitate the exchange of knowledge and resources, and have a strong impact on the quality of the service, the quality of the system, and performance, fundamental aspects of OE (Coo and Verma, 2002). In view of these aspects, we propose the following hypotheses:

H3: There is a direct impact of Strategies on Linkages
H4: There is a direct impact of Strategies on OE
H5: There is a direct impact of Linkages on OE

Appraisal and expression of emotion in the self (SEA) refers to the ability to identify, know, and understand one’s own emotions and their effect on other individuals. To know oneself allows one to influence others through the use of emotions (UOE) and enhance performance and facilitate the accomplishments of predefined goals (Wong and Law, 2002). Therefore, the following hypothesis is proposed:

H6: SEA is positively related to UOE

The resulting hypothesized model is shown in figure 1.

Research method

This confirmatory-correlational research aims to determine the relationship between the different variables and explain and quantify the different observable facts. Accordingly, following Hair et al (2010) and Tabachnick & Fidell’s (2019) recommendations, a survey instrument, measurement constructs, and best model-fit were developed and applied. A self-administered survey questionnaire was designed, starting with a demographic section (industrial sector, size of the company, education area, and work area) followed by a conceptualized set of variables (Strategy, Linkages, Emotional Intelligence, and OE) to build a model that was tested using both descriptive and inferential statistical analysis once the data was collected. The model's variables were rated with the use of a 5-point Likert-style scale (Strongly Agree–Strongly Disagree). 150 usable questionnaires were collected. The average mean values of the statements’ ratings were used to generate the structural equation model. This methodology was chosen as it fits the requirements of this research and allows the analysis of latent variables and their relationship and the required sample is met by the collected data (Nachtigall et al., 2003).

Confirmatory factor analysis (CFA) was used to determine the relationships between observed and continuous latent variables and to check and confirm the overall model fit (Cooksey, 2007; Hair et al., 2010; Tabachnick and Fidell, 2019). Factor loadings were estimated, items loaded on only one construct (i.e., no cross loading) and latent constructs were correlated (equivalent to the oblique rotation in exploratory factor analysis). The internal consistency was confirmed using Cronbach’s alpha coefficient and the items-to-total correlation. All constructs yielded alpha values greater than 0.7, which is the cut-off level set for basic research (Nunally and Bernstein, 1978).
Results
Initial results (see Figures 1 and 2, and Table 1) suggest that there is a significant predictive relationship between SEA and Strategies, confirming H1a. This result demonstrates the important role of self-emotion appraisal in the development of innovative strategies. Due to the fact that the SEA concept relates to the ability of the individual to understand their own deep emotions and the ability to express them naturally, individuals with high SEA will better formulate, understand, and apply strategies, and do so better than individuals with low SEA. SEA also has a significant impact on Linkages, confirming H1b. This finding means that the use of an individual’s emotions is necessary to build up relationships with providers, customers, stakeholders, and other employees of the company. Moreover, SEA is positively related to UOE, confirming H6 and the EI theory (Wong and Law, 2002) that the ability of individuals to understand their deep emotions influences the individuals’ use of emotions for a better performance. Interestingly, SEA has no impact on OE, therefore rejecting H2a.

</tbody>
</table>

The impact of UOE on Linkages and Strategies is insignificant, rejecting H1c and H1d. However, UOE has an important impact on OE and confirms H2b. The use of emotions to facilitate performance is important to the processes developed by the individual and confirms that this concept relates to the ability of the individuals to use their own emotions to enhance personal and collective performance. Individuals with a high UOE, tend to be more focused on being operationally effective, but this is not the case for SEA. However, there is an impact of SEA on OE indirectly through the appropriate use of emotions (UOE). The fact that UOE has no direct impact on linkages and networks indicates that the communication among employees and customers is impersonal. Today’s relations between the individuals constituting the organization’s customers and suppliers are through e-mails and electronic media, and it is not possible to read the other’s emotions. Individuals with low emotional intelligence find it difficult to interact with clients and suppliers.

Strategies have no direct impact on OE, rejecting H4. However Strategies do have a strong and positive impact on Linkages, confirming H3. Additionally, Linkages has a predictive power on OE, confirming H5. Therefore, the impact of Strategies on OE is indirect through the establishment of linkages and networks in the organization.
Conclusion
This study shows the importance of emotional intelligence in strategies, linkages, and operational effectiveness. The results of this study indicate that there is a gap between what the organizations strategically planned for innovation and operational effectiveness and the emotional intelligence of the employees of the studied organizations. Additionally, this result shows a lack of appropriate introduction of innovative initiatives as explained by Tidd et al (2013), probably with a corresponding lack of appropriate dissemination of strategy, so employees do not have the opportunity to assimilate them and work towards the achievement of the strategic plans.

The fact that there is an indirect impact of strategies on operational effectiveness through the linkages, partially confirming H3, indicates that the studied organizations need to improve their strategic formulation.

Another important finding is related to the fact that there is a disruption in the communication channels between the individuals in the organizations and the suppliers and customers, probably because of the increased use of technologies. Therefore, it is necessary to improve the communication paths so individuals can interact with peers without needing to interpret the others’ emotional intelligence.

It is also important to note the strong relationship between the use of emotions and operational effectiveness. This study demonstrated that individuals are paying attention to the role of key performance drivers such as cost, quality, reliability, flexibility, and speed. Therefore, organizations need to dedicate adequate training and dissemination of the strategic role of operational effectiveness to achieve a sustainable competitive advantage.

Future studies could further explore the alignment between strategies and innovative initiatives such as products or services, paradigm, position and process innovation, and operational effectiveness. Decomposing operational effectiveness into specific performance objectives such as cost, quality, reliability, flexibility, and speed could be the key to better understanding how emotional intelligence and operational strategies can interact effectively. A closer look at such interactions would certainly contribute to the sustainable performance of the organization.
by achieving operational effectiveness. By gaining such understanding, strategic management would benefit from a more comprehensive insight into performance determinants.

Abstract

The 4.0 technological wave is re-shaping the manufacturing context, often referred to as Smart Manufacturing. The new smart technologies can foster a more human-centric approach, enabling the emergence of proactive behaviours in manufacturing context. This study aims at inquiry if a particular type of proactive behaviours – namely job crafting – is enabled by smart manufacturing technologies. Findings about two Italian manufacturing companies implementing similar technologies show that digitalization in manufacturing can enable a shift towards the autonomy and professionalism of operators, which in turn creates opportunities for workers to actively participate to processes and redefine their role, leading to improved performance.

Keywords: Industry 4.0, Job Crafting, Proactive Behaviours, Smart Manufacturing

Introduction

The widespread adoption of networked digital technologies to integrate manufacturing processes, that goes under the umbrella of Smart Manufacturing, and the new smart technologies introduced in the manufacturing processes have the traditional approach of manufacturing work. In fact, manufacturing companies are usually exploiting technology to foster standardization and control, pursuing production flexibility instead of labor flexibility (Gordon et al., 2018). However, preliminary empirical studies on the impact that Smart Manufacturing have on organization of work show that this new technological paradigm can enable the creation of new types of jobs, for which operators are more involved, having greater autonomy and responsibilities, and performing non-routinized and cognitive tasks (e.g. Romero et al., 2016; Cagliano et al., 2018).

In such scenario, smart technologies may activate the possibility for the operators to put in place proactive behaviours (Romero et al., 2016), intended as a set of actions that aim at redefine the content and tasks of one’s work, together with the proactive re-definition of role boundaries (Wrzesniewski & Dutton, 2001).
The present study aims at inquiring if 4.0 technologies enable proactive behaviours in manufacturing settings, by collecting and analyzing qualitative empirical evidence in two different manufacturing companies implementing similar technologies.

Theoretical background

Proactive behaviours in job design
In the last 30 years, the emergence of new organizational forms which should be coherent with the competitive business scenarios in terms of organization of work and organizational design, has been a theme of interest for scholars (Whittington et al., 1999). In an environment characterized by hyper-competition and rapid-changing market requirements, the necessity emerged for firms to increase their flexibility and their capability to maintain a company-environment fit over time (Fjeldstad et al., 2012; Schreyögg & Sydow, 2010). In order to build their dynamic capabilities, organizations have shifted towards configurations emphasizing the role of the employee, which was brought at the centre or the organizational architecture (Fjeldstad et al., 2012). Within this context, the phenomenon of workforce’s proactive behaviours has gained increasing momentum, becoming a main research field as well as a managerial focus (Rofcanin et al., 2016).

A relevant construct related to proactive behaviours is job crafting, defined as “the physical and cognitive changes individuals make in the task or relational boundaries of their work” (Wrzesniewski & Dutton, 2001). It is a proactive, bottom-up process initiated by employees without management involvement, which requires continuous adjustments of tasks and role boundaries (Berg et al., 2010). A remarkable feature of this phenomenon is that it describes the ways employees spontaneously participate in the design of their own roles (Hornung et al., 2010), complementing the more traditional perspective of job design as defined by top-down management action (Parker et al., 2017). By autonomously altering the tasks and content of their job, employees pursue satisfaction of individual needs and motivations, ultimately impacting on job meaning and work identity, i.e. how they conceive and the way others conceive their role and purpose within the organization. Wrzesniewski, & Dutton’s (2001) construct therefore departs from the traditional view of job as a source of sustenance and security, towards a perspective in which people conceive their job as the locus where the individual has the possibility to develop a meaningful role and find satisfaction in life (Kooij et al., 2017; Melè, 2005; Wrzesniewski & Dutton, 2001). Wrzesniewski & Dutton’s conceptualization (2001, 2010) also outlines different forms of crafting: (i) crafting physical task boundaries, altering the scope and nature of existing tasks or introducing additional tasks; (ii) crafting cognitive boundaries, redefining their perception of single tasks and relationships or reframing the perception of their job as a meaningful whole; (iii) crafting relational boundaries changing the existing relationships or creating additional relationships.

The conclusions resulting from studies on job crafting behaviours are that employees who take the initiative to change their job role and work environment are likely to contribute more to organizational effectiveness (Tims et al., 2012), and that these behaviours can be stimulated or hindered by the effective definition of job characteristics (Rudolph et al., 2017). Nevertheless, studies about job crafting behaviours have mainly explored phenomena in front-end service job roles and in contexts of relative static nature of the work environment (Bakker et al., 2012), while we lack research about manufacturing companies. A possible explanation for this aspect is the relatively high formalization and control of manufacturing jobs, which hinders the possibility of
proactively changing the boundaries of one’s job (Gordon et al., 2018). The new technological wave related to digitalization and Smart Manufacturing, which can re-shape organization of work towards a more flexible environment (Hirsch-Kreinsen, 2014, 2016), may create the opportunity and interest to extend the job crafting literature to industrial settings.

**Smart manufacturing and proactive behaviours**

As modern digital technologies possess strong implications on job characteristics (Khatri et al., 2010; Parker et al., 2017; Tafti et al., 2007; Wilkesmann & Wilkesmann, 2018), there might be a new interest to assess the impact of digital applications over job crafting, which determines additional, often unexpected effects on organizational performance.

As reckoned by many authors, the manufacturing sector is currently under a significant paradigmatic shift – often acclaimed as a new industrial revolution, which is leading to the introduction of several smart and connected technologies within the plant. Smart Manufacturing - one of the labels used to identify the new paradigm based on Industry 4.0 technologies - refers to the pervasive implementation and application of networked, information-based technologies throughout the enterprise manufacturing and supply chain (Edgar et al., 2012; Hirsch-Kreinsen, 2014, 2016). These information-based technologies show significant variations in terms of application and complexity and, for this reason, several classifications have been proposed. For example, they can be groped in four main technological clusters: (i) data, computational power and connectivity; (ii) analytics and intelligence; (iii) human-machine interaction; (iv) and digital-to-physical conversion (Wee et al., 2015). Smart manufacturing has spread fast in European political agendas, as showed by the data about national Industry 4.0 policies and public funding in Europe, with companies showing a growing interest toward this phenomenon (European Commission, 2017). While early literature and reports point out the cost-saving and performance improving effect of the technological applications (Bauer et al., 2016; Rüßmann et al., 2015), more recent literature is directing towards the organizational changes that those technologies enable or require both at the micro and macro level (Cagliano et al., 2018; Longo et al., 2017; Seghezzi, 2015, 2016; Wilkesmann & Wilkesmann, 2018). The main underlying theoretical lens adopted when studying these aspects is the socio-technical theory (Trist et al., 2013), which sees the design of organizations as the result of the complex relationship between: (i) opportunities and constraints deriving from the available technology and the production process to be implemented, and (ii) opportunities and constraints of social nature, namely the actors involved and their objectives and needs.

While the previous industrial revolutions had the effect of automating physical and cognitive routine tasks, scholars address this revolution as automating and supporting non-repetitive physical as well as cognitive tasks, with robotics and algorithms performing increasingly better than humans in tasks as data collection and analysis, as well as physical manipulation (Berger & Frey, 2016; Frey & Osborne, 2013; Manyika et al., 2017). As a result, the skills composition of jobs is shifting towards digital and human-machine interaction capabilities (Bughin et al., 2018), but also towards soft skills as problem solving, critical thinking, teamwork and creativity (Bughin et al., 2018; Lorenz et al., 2015; World Economic Forum, 2016).

From an organizational perspective, the discussion has increasingly focused on the emergence of alternative scenarios, i.e. the automation and job polarization versus complementarity (Hirsch-Kreinsen, 2016). In the automation scenario many jobs are performed by machines and algorithms, and the remaining human activities are governed and ruled by autonomous machines. The operator’s work is therefore subordinated to the
directives of the technological system and jobs are characterized by a low number of simple operational activities. Within this scenario there is still space for few jobs characterized by high autonomy and cognitive content, mainly related to the design, implementation and training of the autonomous machines. In the complementarity scenario instead, automation concerns manual and cognitive routinized task, while operators would have full control over the technological systems and would use it to collect information to better control and to improve sub-processes when the right circumstance occurs. We would assist to a reduction of low skilled jobs but there would be an increase of both highly skilled personnel and of operators with average technical qualifications, able to communicate and interact with advanced digital tools (Autor et al., 2003) and a high number of multitasking positions - characterized by a high degree of structural openness, a very limited division of labour and high flexibility (Böhle and Rose, 1992). Overall, this organizational model is referred to as swarm organization (Hirsch-Kreinsen, 2014, 2016).

Early empirical research has investigated the application of single technologies within the industrial plant in order to shed light to the organizational consequences of Smart Manufacturing at the macro-level. Wilkesmann & Wilkesmann (2018) have proposed a first attempt to map the different smart technologies according to their impact on four organizational and job characteristics, namely degree of formalization, distinctness of control authority, location of knowledge, degree of professionalization. What emerges from qualitative research is that different applications are likely to have different impacts, which can lead the organization toward more mechanic or more organic settings (Wilkesmann & Wilkesmann, 2018). Technological complexity of smart manufacturing implementation - indented as the number of technologies implemented and the level of integration between different processes enabled by the technologies – influences the adoption of more mechanic or organic forms of organization of work. In fact, a higher level of technological complexity is associated to a decentralization of decision making and a reduction in the number of hierarchical levels (Cagliano et al., 2018).

At the individual level, smart technologies are increasingly supporting humans’ physical, sensorial and cognitive capabilities, enabling them to cope with an increasing complexity of the external and internal environment (Longo et al., 2017; Romero et al., 2016). At the operational levels, the operator 4.0’s work results in a higher involvement in the production process, with greater autonomy and responsibilities over the plant. A characterizing feature of the worker 4.0 will be to perform non-routinized and cognitive tasks, which require real time adaptation (Romero et al., 2016). Supporting empirical research indicates strong changes in the job design at the operational levels of industrial companies, including an increase in autonomy of decision making and autoregulation, increase of teamwork and collaboration, job polyvalence, an increase of the cognitive content of work, especially when technological complexity is high (Cagliano et al., 2018). Results clearly point towards a professionalization of roles, with higher competences, more value-adding tasks and more responsibilities, decision making and problem solving. The new operator 4.0 emerges as the responsible of automated workstations, which is tasked with workstation’s machines control and is able to perform operations of standard maintenance, machines’ stops resolution and optimization of the process for which she/he is held responsible (Bartezzaghi et al., 2017; Cagliano et al., 2018).

Despite these findings, recent research presents several gaps related to the content of work and about the characterization of the new role of the smart operator. First, the general consensus about reduced job formalization, higher autonomy and higher complexity of work accounts for the importance to develop more studies about the proactive behaviours that are deemed to flourish within the industrial workplace. Second,
while researchers have extensively investigated the relation between job characteristics and proactive behaviours as job crafting, few studies have analysed the relation between technology and human proactivity, with even more paucity considering the smart manufacturing case. Finally, there’s a need to develop further research about smart technologies’ implications on organization, clarifying which organizational designs will be justified and enabled by the fourth industrial revolution.

Based on the above, the present study aims at exploring the following research question: “Do Smart Manufacturing technologies enable the emergence of proactive behaviours through job crafting?

Methodology

Sample selection
In order to gain insights on the scope of research and in line with the exploratory nature of the research questions, case studies on two different companies implementing smart manufacturing has been carried out (Eisenhardt, 1989; Yin, 2003). A case study is an empirical methodology investigating a phenomenon within its real context (Denzin and Lincoln, 1994), particularly appropriate to cope with situations where there are more variables of interest than data points and where new phenomena are inquired (Yin, 2003). The two selected companies are Red, a family-owned mid-sized company located in Italy and producing mechanical components for home appliance producers, and Blue, a mid-sized company producing mechanical components for the automotive industry.

To select the companies, we looked for companies sharing similarities in: (i) the industry and the organization of work at the plant level, and (ii) in the implemented 4.0 technologies. Concerning the industry and organization of work, both companies are manufacturing companies producing mechanical components (although for different applications). Concerning the organizational structures, the two plants are characterized by a traditional hierarchical structure, in which there are four hierarchical levels: the plant responsible(s), the production departments responsible, the supervisors, and the operators. As far as the implemented technologies are concerned, we looked for companies putting in place similar technological applications among the many different Smart Manufacturing technologies. In particular, we selected two companies exploiting Internet of Things and Analytics to collect data on the production process in real time, in order to provide up-to-date data and analyses about different performance dimensions such as the Overall Equipment Effectiveness (OEE), quality performance, productivity. These analyses are available in the plant thanks to a dashboard displayed on smart screens positioned in different parts of the production plant, in order to be consulted by both managers, supervisors, and operators. In the Red case, all the workforce on the plant have also a wearable smart watch that reports the main parameters of productivity in real time and that signal them the alerts about problems and unexpected stops on a specific machine.

Data sources and analysis
In order to ensure reliability, multiple data sources were employed, namely semi-structured interviews, observations, and archival data (Denzin & Lincoln, 1994; Miles & Huberman, 1994). Semi-structured interviews were carried out with different actors and roles for both the companies, including top management, Human Resources manager, responsible of the plants, responsible of Smart Manufacturing projects and their implementation in the company, supervisors and operators. A total of 20 interviews was
carried out (11 for Red and 9 for Blue). Each interview followed a semi-structured interview protocol organized in macro-sections and aimed at gathering information on different aspects such as (i) the background of the interviewee, (ii) the Smart Manufacturing technological characteristics and applications, (iii) the characteristics of the individual jobs in the plant in terms of nature and variety of tasks performed, level of autonomy and interaction with other colleagues, (iii) the emergence of proactive behaviours, (iii) the overall quality of work and well-being of the interviewed people. Each interview lasted from 45 to 90 minutes and was recorded and transcribed. In addition, researchers and interviewees have often engaged in off the records discussion during coffee breaks and lunches, providing additional information that has been transcribed after the meeting and that added further insights about proactivity of the plant personnel interacting with the 4.0 dashboard. Observations took place in both companies after the interviews were completed and consisted in two visits, one in each of the two plants. Both visits lasted two hours and consisted in directly observing the work of the operators and supervisors on the production lines, and their interaction with the dashboards. We also had the opportunity to ask questions to the supervisors and to the operators during their breaks at the coffee machines located in dedicated parts of the plant. To keep track of our observations, we took field notes in real time that were then reviewed after the end of the visit. Finally, we reviewed also archival data such as internal company reports, organizational and plant charts, company presentations, company manuals and job descriptions. These archival material was used to further validate the description of organization of work in the two companies.

The data collected with interviews, observations and archival data were analyzed by the research team through a coding process and with an inductive approach (Strauss & Corbin, 1998; Gioia et al., 2013). Figure 1 summarizes the structure of the data.

Figure 1 – structure of the data
Findings
Figure 1 summarizes the overall findings. Empirical evidence showed how job crafting for operators was enabled both directly, thanks to the introduction of the 4.0 technology, and indirectly, thanks to changes in terms of organizational design that further foster job crafting behaviours. Moreover, findings show that job crafting enabled by 4.0 technology has also improved performance both in terms of plant productivity and efficiency, and in terms of employee-level outcomes. Findings on these different aspects will be now illustrated describing: (i) the emergence of job crafting behaviours; (ii) the organizational changes fostered by the new technology; (iii) the impact on performance both at the plant and employees level.

Emergence of Job Crafting Behaviours
Our findings show that the adoption of a smart dashboard available for all operators which provides up-to-date information about the production process, enables job crafting behaviours. In both Red and Blue cases operators are able to change the boundaries of their individual job in terms of task, cognitive and relational boundaries.

In terms of task boundaries, the better understanding of the production process leads operators to better organize their activities. The smart system implemented in the plant enabled operators to propose new tasks to be performed, altering both the number and the types of activities they carry out, in both cases, as indicated by the following exemplary quote: “The system tells me the average time of production of the unit. So I know how much does it take, I can plan my scheduling in a much more independent way, I do not have to wait for the supervisor to tell me what I should do” [Operator, Red].

Moreover, the smart dashboard and sensors system enabled a redefinition of cognitive boundaries of the tasks for operators. The availability of information and the visibility of the overall production system enabled for operators a shift towards professionalism, since they see themselves as data users and not just data collectors, consequently carrying out problem solving, proposing suggestions for improvements and asking for more professional training. The following quote is exemplary of this aspect: “Each morning, I call for a meeting with my team and I show them the analysis about their production of the day before. They are the ones that are able to explain to me why we had such a performance, and now they do it” [Supervisor, Blue].

In terms of cognitive boundaries, the smart dashboard and sensors system enabled the opportunity for operators to change some aspects related to numbers and types of relational interactions, both vertically and horizontally, as indicated by the following exemplary quote: “When I was operator 20 years ago it was difficult to interact with the production responsible or the department manager, this was possible only if there was a major mechanical problem. Now I discuss a lot with operators about data and process functioning, and there’s a strong “bottom-up” interaction with the operators, and for me the same thing happens with the manufacturing manager” [Department Manager, Blue].

Organizational changes
Empirical evidence showed that the smart manufacturing technology was acting not only directly on the enablement of job crafting behaviours, as illustrated above, but also indirectly through some other organizational changes that can further foster proactivity. In particular, these changes concern the hierarchy, the location of knowledge and the organizational culture. Here some representative quotes of these aspects: “One of the two most important activities of the HR function is to give decision-making competencies. The work that has been done was to increase line responsibilities, to let semi-important
decisions be taken a bit at lower levels” [HR Manager, Red]; “Every operator can come and see any time the performance of the plant, and of each machine, any time they want” [Supervisor, Blue]; “Having the machine trends under sight you can understand your position in respect to targets, and what are the problems that are slowing down your yield… because without data many times you make reasoning with your gut” [Department Manager, Blue].

**Improvement of performances**

Finally, evidence shows that enabling job crafting behaviours has a positive impact both on employee-related performance and plant performance. About employee-related performance, positive effects on employee-related outcomes, especially for operators, are highlighted by several interviewed roles. Job satisfaction seems to have increased and in some case operators express the feeling of an increased level of creativity in their daily activities: “Work now is more dynamic, and we’re not strictly bound to the machine. The system signal that there is a problem, and sometimes solving it means find a new way of doing things, I can experiment much more than before” [Operator, Blue].

About the plant performance, the objective measures of productivity and efficiency show significant improvements in both cases. The perception of managers and operators is that this improvement is also connected to job crafting behaviours and to the changes in organizational design, as the following quote indicates: “Performance has for sure increased, as a consequence of the fact that not only department managers and supervisors, but also operators take proactive initiatives to solve problems. The machine is still the same. The difference is the operator that understands before if something is going wrong, and intervene before something breaks” [Department manager, Red]

**Discussion**

Our findings show a relation between the introduction of smart technologies and the enablement of proactive behaviours within the manufacturing plants. This is possible thanks to both the direct availability of data and the redesign of the organization towards higher job autonomy, task variety and cognitive work for the 4.0 operator. In turns, job crafting, coupled with the redesign of the organization, leads to better performance at both individual and organization level. This finding is pretty significant and novel for the literature, since it allows to broaden the literature on proactive behaviours and job crafting to the manufacturing sector, in particular within the emerging context of smart manufacturing.

**Job crafting supporting the swarm organization for smart manufacturing settings**

From a broader organizational perspective, this study offers an interesting contribution to the debate about the possible organizational scenarios for smart manufacturing, summarized in the polarization versus swarm organization scenario (Hirsch-Kreinsen, 2014, 2016), supporting the latter. The application of extensive analytics and the diffusion of data at the lower organizational levels through different human-machine interfaces configures a shared information infrastructure connecting the operators, and incorporates the protocols and practices for using and sharing knowledge within the organization. As each operator is held responsible for a specific part of production activities, autonomy is strong, and upper-level management and technical staff intervenes only for major problems to occur. Control authority becomes more horizontal and organized in networks of discussion about common goals and potential improvements. The redesign of work
towards a swarm organization is partly a conscious work redesign action taken by (HR) managers, but partly a consequence of job crafting behaviours enacted by operators thanks to the enabling role of 4.0 technologies. With the support of smart technologies, operators take proactive action to cope at any time with unanticipated disruptions and customized actions in conditions of high volatility.

Thus our study not only contributes to give empirical support to the emergence of the swarm organization scenario that has been theoretically postulated by some authors (Hirsch-Kreinsen, 2014, 2016), but also provides a deeper understanding of how this phenomenon occurs and relates this organizational change with the emergence of workers’ proactive behaviours. Thanks to this, the literature on proactive behaviours and job crafting (Bakker et al., 2016) can inform the emergent literature on new organizational models for smart manufacturing.

**Smart manufacturing and job crafting: meaningfulness of work in manufacturing setting**

The results of our study also provides an additional contribution to the literature on work meaningfulness. Previous research has already outlined the role of “datification” in providing accountability for jobs, which helps professionals in gaining awareness about performance achievements and provides the possibility to showcase them to their relational network, increasing overall job meaningfulness and work identity (Stein, Wagner, Tierney & Newell, 2018; Wrzesniewski & Dutton, 2001). Similarly, this research shows a progressive professionalization of roles among operators. Professionalism was already discussed in literature of smart manufacturing, that describes the new 4.0 operators as performing non-routinized cognitive tasks that require capabilities of real-time adaptation and improvisation in order to handle rapid changes (Seghezzi, 2015, 2016b; Bughin et al., 2018; Longo et al., 2017). Coherently with the literature, in our case studies operators take responsibility over complex tasks previously solved by professionals, and are supported by information and 4.0 operation technologies in performing decision making, problem analysis and problem-solving. In addition, the “datification” of machines performance grants operators’ awareness and visibility on their and others actions, with the possibility to demonstrate to the organization their professional abilities and gain satisfaction. This study contributes to show that job crafting is also used by operators to craft their jobs to accommodate their own concept of professionalism and meaningful work, and to accommodate their need of positive self-image (Berg et al., 2010; Wrzesniewski & Dutton, 2001).

These behaviours are manifested firstly in an engagement towards raising performance, which push them to “raise the bar” towards work quality and to search improvement solutions to enhance productivity KPIs. In addition, as the system shares transparently the performance of each employee, in both cases managers have assisted to episodes of positive competitions towards the highest OEE, in an attempt to self-define the owned professional identity. Finally, increased professional awareness lead to an additional involvement in the company, engaging workers in continuous improvement initiatives and activities of collaboration and information exchange.

**Managerial implications**

The importance of this research in informing managerial action pertains to different areas. First of all, this research has demonstrated the importance of organizational variables and their impact over proactive behaviours, which is in most cases neglected from companies during the implementation of smart manufacturing initiatives. This can lead to different unexpected results in job design and in operators’ job crafting, which translates in unexpected problems and missed opportunities along the digital roadmap. An assessment
of the necessary changes on workers’ roles, of their arising necessities and of the possible actions and benefits of involvement can unleash much higher performance from Smart Manufacturing projects and lower payback times from investments. Moreover, the study underlines the importance that a pervasive transformation leveraging smart technologies has over proactive behaviours via the redefinition of organizational characteristics. Consequently, the anticipated planning of organizational initiatives towards proactive behaviours can be considered as fundamental.

Second, the HR function has been shown to be a key actor in the smart change, possibly as relevant as the operations and the IT function to lead the transformation in the right direction and to organize the necessary training for workers to embrace their new smart roles. Workforce skills should be developed in parallel with smart technology in order to win the societal challenge of the skill gap (Berger & Frey, 2016; Bughin et al., 2018).

Lastly, management should be aware of the fact that the way technology is developed impacts proactive behaviours. This is particularly visible considering the importance of user-friendly design and its importance for machine-human interfaces. The design of intuitive interfaces for smart tools impacts the possibility of enabling job crafting behaviours.

Conclusions
As one of the first studies about proactive behaviours in job design in the context of manufacturing, and the first in smart manufacturing settings, this study has provided early insight about the future of manufacturing jobs and organizational models, shedding light over the possibility for the emergence of proactive behaviours in such contexts, opening the way for higher autonomy and freedom of industrial jobs. The freedom of operational decision, the responsibility towards problem-solving and the operators’ involvement in the digital transformation are creating more and more opportunities to craft job roles. As operators’ see the possibility to own their job and improve their work life, industrial companies acquire the unprecedented opportunity to involve more workers in the organizational life.

Abstract

The majority of organizations regularly face disruptions, resulting in substantial financial and reputation damages. To solve organizational disruptions, multiple teams have to effectively collaborate between each other. Contrary to the current consensus that increased collaboration benefits team performance under all disruption circumstances, we propose that teams should align the way they collaborate with the disruption characteristics. We use a social network approach to test the moderating effect of disruption complexity on the relationship between collaboration centralization and disruption duration. Research aims to generate new insights about how proper disruption management might help organizations improve their collaboration in face of disruptions.

Keywords: Resilience, Collaboration, Network analysis

Introduction

Many organizations face disruptions that can seriously affect their performance and business continuity. Dealing with such disruptions is often beyond the capacity of any single team within the organization. Indeed, several organizational teams often need to collaborate with each other to develop well-integrated countermeasures that can help minimize the disruption’s adverse consequences for the overall organization (Scholten & Schilder, 2015; Hohemstein et al. 2015; Tukamuhabwa et al., 2015). While the literature within supply chain (SC) management has been optimistic about the effectiveness of collaboration, less is known about how teams can collaborate effectively during varied disruptions.
Our main insights are based upon team research (e.g., Tröster et al., 2017) and follow an argument similar to the contingency approach in SC management (e.g., Giménez et al., 2012) that shows that the type of SC integration depends on the level of SC complexity. Specifically, we examine how can teams optimize their collaboration processes to effectively deal with disruptions. We suggest that success of disruption resolution depends on the effective alignment between teams’ collaboration and type of disruption. We argue that disruptions with far-reaching consequences (i.e., severe disruptions) require more centralized collaboration structures in which one or few team members orchestrate and execute collaboration on behalf of all teams. For less severe disruptions, by contrast, we expect more success for teams that rely on open and unrestricted collaboration, facilitated by more decentralized collaboration structures.

Methodology
We test our model using data from a public water-supply company. This is a suitable context, as ruptured water pipes, broken-down pumps, and other sorts of disruptions regularly threaten the supply of water to customers, and accordingly, the continuity of the water supply company. In case of such disruptions, teams from the public water company have to collaborate to ensure the company’s high water-delivery standards. Collected data consists of detailed information on the location, pipeline diameter, and total time of no water supply associated with over 8000 disruptions. We treat the disruption duration as dependent variable, and disruption severity as a moderator. In addition, we obtained anonymized information on the telephone communication between organizational teams that dealt with the disruptions, and used it to measure centralization of collaboration (Freeman, 1979), serving as an independent variable. We will treat these telephone records as social network data. Centralization in this study was calculated using Freeman’s approach (Freeman, 1979), as the average difference in centrality between the most central actor and that of all other members in the network. In our study, actors communicating during each disruption constitute a network, and we calculate centrality of coordination for each disruption using the number of the calls from and towards each actor.

Findings
Preliminary analysis during the initial phase of data collection provided support for our main hypothesis. We found a significant interaction effect between centralization, disruption severity, and disruption duration ($B = -30616.68$, $SE = 18552.26$, $p < .10$).

Conclusion
This study contributes to existing research in several ways. While collaboration has been studied before, the present study provides a more nuanced and novel view on how can teams effectively structure collaboration processes to enhance their responses to different types of disruptions. It shows that the structure of the collaboration processes needs to be adapted to the disruption, which challenges the widely held belief that collaboration is beneficial in all situations. A second contribution lies in the empirical data used. So far, empirical work on resilience has been limited (e.g., Tukamuhabwa et al., 2015) and the scarce empirical research that is available has mostly relied on subjective data. The present study, however, employs objective data on real teams dealing with real disruptions. Practically, our study helps administrators to make well-informed choices on how to structure collaboration between teams during disruptions.

Abstract
Most of the authors who researched on workers’ capacity management, in the field of Dual Resource Constrained and Workload Control, were mainly oriented to increase the overall worker’s capacity of the system through subcontracting, overtime and new workers hiring. Different When, Where and Who rules have been tested when investigating worker’s arrangements rules. A rule, namely Baton Bumping Zone Balancing, has been proposed by Protzman et al., (2016). However, it has never been tested in terms of numerical evidence. In this research paper, authors propose a methodology to assess the impacts of this new rule in a pure flow shop.

Keywords: Baton Zone Balancing, Labour Flexibility, Worker’s Allocation

Introduction
In the light of increasing worldwide competition and uncertainty of markets, interest in manufacturing flexibility is increasing. The issue of manufacturing flexibility has long been cited as a key competitiveness measure (Boyle, 2006) and a strategic sourcing. This is particularly important in today’s high-tech business environment, characterized by short product life cycles, small lot sizes, changing product mixes and quick response. In literature, there exist many conceptions of flexibility and its definition and measurement remain a research issue.
Labour flexibility, or workforce flexibility, is considered as a managerial tool to achieve volume flexibility in production. Volume flexibility is recognised as a strategic mean to face uncertainty in markets and growing global competition (Goyal and Netessine, 2009). The role of the workforce in supporting industrial objectives, like volume flexibility, is recognised in many studies (Hopp and Van Oyen, 2004; Digiesi et al., 2009).
One of the fundamentals of lean management is the multi-skilled employee, having the competences, experience and knowledge to perform many different simple and complex tasks. The most dominant stream of research on workforce flexibility has been on dual resource constrained (DRC) production systems (Hottenstein and Bowman 1998). In dual resource constrained systems, two resources are considered to be constraining factors for the level of output: labour and machines. For smooth operation of these systems, attention should thus be given to cross-training and labour allocation rules.

The implementation of worker arrangement mainly depends on the decisions taken regarding the following three aspects:

- **When rules or control rules.** These rules indicate when the worker is available to move to another work station to process a task.
- **Where rules or assignment rules.** They define the policy by which a worker is assigned to a particular station.
- **Who rules.** These rules determine which worker, among the available ones, is transferred to another workstation.

A new approach for line balancing and worker’s arrangement never investigated has been introduced theoretically by Protzman et al., (2016) and takes the name of Baton Zone Balancing (Bumping). It allows to obtain One-Piece Balanced Synchronized Flow. According to it, the production line follows the flow of the order regardless of the times at each station. Protzman et al., (2016) provided a theoretical description of Baton Zone Balancing (Bumping), with no empirical evidences of its benefits. The purpose of this paper is to propose a simulation model through which assessing by means of numerical evidences the impact of Bumping approach in a pure flow shop.

The remainder of the paper is structured as follows: in the literature review section, authors highlight the main findings related to worker’s flexibility and the Bumping model, as theorized by Protzman et al., (2016); then in the Methodology section, the presentation of the simulation model, that will be used to collect the results, is depicted.

**Literature Review**

The present section will be devoted to present the survey of the literature concerning the labour flexibility, while the second part will be dedicated to present the Bumping model, as presented by Protzman et al., (2016), as a new possible labour flexibility policy.

**Labour Flexibility**

Labour flexibility, or workforce flexibility, is considered as a managerial tool to achieve volume flexibility in production. Volume flexibility is recognised as a strategic mean to face uncertainty in markets and growing global competition (Wernerfelt and Karnani, 1987, Goyal and Netessine, 2009). According to Małachowski and Korytkowski, (2016), a competent workforce is a source of competitive advantage for a company. Indeed, since machineries, equipment and tooling can now be purchased by anyone with the appropriate resources and all of them are readily available, the factor that differentiates companies is the know-how of their employees, which also forms the company’s main asset. One of the fundamentals of lean management is the multi-skilled employee, having the competences, experience and knowledge to perform many different simple and complex tasks. Employees are a source of flexibility as they are capable of seamlessly change their roles according to the company’s needs (Womack and Jones, 2010). In a company with a multi-skilled workforce, planning focuses on the needs of the customer, not on the
capabilities of the staff, and this leads to a reduction in the number of idle hours. An experienced and well-trained multi-skilled workforce translates directly into higher productivity, better quality and lower costs. Worker flexibility is desirable when Dual Resource Constrained (DRC) systems are compared directly to machine-limited systems that, by definition, have zero worker flexibility. DRC shop with a flexible workforce can have lower inventories and better due date performances than a shop with no cross-trained workers, since workers can be rotated throughout the shop to respond to changing workloads (Krajewski et al., 1987).

The introduction of the worker flexibility in production systems mainly depends on the decisions taken regarding the following three aspects:

- **When rules or control rules.** These rules indicate when the worker is available to move to another workstation to process a task. In the literature two ‘When’ rules are prevalently presented. The first is the Centralised rule, according to which workers can be transferred to other workstations after the completion of the current job, even if the queue in the current workstation is not empty (Darwin et al., 2009, Sammarco et al., 2014). The second is the Decentralised rule, where workers can be transferred to other workstations only when they are idle, that is when the queue in the current workstation is empty. As reported in Sammarco et al. (2014) the ‘When’ rule choice can affect both system and human performances. If more production is requested, the ‘Decentralised’ rule is a suitable assignment even if a worker spends more time in the same workstation. Thus, the switching rate decreases and the utilization increases. As a consequence, the rest time to recover from fatigue is reduced, with a negative impact on stress and musculoskeletal disease, that leads to the occurrence of safety issues (Tucker, 2003). On the contrary, the ‘Centralised’ rule permits many micro-breaks during more frequent changes of station. This aspect increases the variety in work tasks, but at the same time causes a reduction of flow time and WIP. Ultimately, the choice of the when rule depends on the strategic objectives of management, particularly if they push forward the optimization of throughput time or WIP. When production volume is more important, then the ‘Decentralised’ rule provides superior performance. On the other hand, if reduction in WIP costs is a priority (Yang and Posner, 2010), the ‘Centralised’ rule is superior.

- **Where rules or assignment rules.** They define the policy by which a worker is assigned to a workstation. Worker assignment rules have been extensively examined in the literature and most of the ‘Where’ rules investigated are based on due date evaluation, bottlenecks, amount of total processing time of products in a queue, and other product timing indicators. ‘Where’ an eligible cross-trained worker should be assigned has a greater impact on shop performance than the question of ‘When’. In particular, the largest reduction in variance came from assigning eligible workers to queues containing the longest job in the system (LTPT), rather than to workstation with the most jobs in queue (LNQ). On the other side, the longest queue (LNQ) based rule resulted in a 20% reduction in machine and operator idleness, an increase in total output, a reduction of cost per unit of output, and an improvement in delivery performance. LTPT rule performed well in term of improvement of delivery performances and reduction of operators’ idleness. Finally, the rule based on the worker efficiency (WE) proved to dominate all the others. However, the results presented above are frequently associated to pure job shop (Sammarco et al., 2014). Some authors (Sammarco et al., 2014, Bokhorst et al., 2004) argued that it is unlikely that pure jobs shops are found in real companies and the results of these studies can lead to misleading results. As a matter of fact, results achieved through simulations in
pure job shop configuration can be far from the one that can be realized when the flow becomes directed, due to the different nature of the organization. Moreover, in flow shop configurations ‘Where’ rules should be simpler in order to reduce the workers’ reaction time (i.e. the time required to identify the next machine to go to) and to not disrupt production.

- **Who rules.** These rules determine which worker, among the available ones, is transferred to another workstation. As reported in Felan and Fry, (2001), most of the researches neglect the importance of ‘Who’ rules and they rather focus on the other two types of rules, although they play a key role in the daily practice of worker assignment and in almost all DRC systems, choosing between workers is necessary at a certain point. As with other labour allocation rules, the impact of the ‘who’ rule depends on the specific DRC shop modelled. In particular, the average labour utilization, and the types and extent of worker differences, determine the impact of the ‘who’ rule on shop performance. As stated in Bokhorst et al., (2004), ‘Who’ rules may affect flow time performance only in those systems where workers are different in terms of skills. Most of the researchers consider worker skills through two parameters: worker flexibility and worker efficiency. Worker flexibility summarizes the capability to work on different machines. While single-skilled workers are constrained to a particular machine, multi-skilled can be transferred to several machines. It results in a reduction of their idleness, an increase of their productivity and lower costs (Malachowski and Korytkowski, 2016, Felan and Fry, 2001). Concerning the worker’s efficiency, it represents the proficiency of workers to run stations and to process tasks. The level of efficiency is frequently expressed by using values that range between 0% and 100%, and it represents the time workers spend processing jobs divided by the actual reduction of jobs processing times at a given station.

Malachowski and Korytkowski, (2016), demonstrated that cross training particularly fits systems with high workload imbalances as make-to-order companies, since workers can be transferred where they are required the most. Indeed, an important classification may be done between Balanced and Unbalanced production lines. Balanced lines may be defined as lines in which the processing time distribution at each workstation is identical. It is more common, but less precise, to define balanced lines as ones with equal mean processing times. As a consequence, in a perfectly balanced line, all the workstations have equal amounts of work allocated to them and variation in operation times is non-existent. In a truly ideal balanced line, buffers are not necessary since partially completed pieces move from one station to the next at the same pace. In real lines, this kind of balance is difficult to achieve, so work allocation and buffers are used to move lines as near as possible to a balance. Since in these production lines usually each stage of the assembly process takes a different average length of time to complete, they are known as Unbalanced production lines. Different sources of imbalance can be founded; the most common is the Processing Mean Time imbalance. Although several early papers demonstrated that lines unbalanced with respect to mean processing times could outperform balanced lines, many authors studied possible ways to balance these lines. One of these approaches consists in defining the optimal location of the stations according to their mean processing times. Across the Unbalanced Lines literature, most of the results show that placing the faster stations in the middle of the line gives the best performances. This is explained by the fact that the blocking and starving that occur as a result of the slower stations has the most effect on adjacent stations, and therefore, placing them at the extremities of the line only affects one station either upstream or downstream. This setting of the stations in the line corresponds to a ‘bowl’ shaped disposition of the mean
processing times, as described by Hillier and Boling, (1967) in the so-called Bowl Phenomenon. The opposite configuration, called ‘Inverted Bowl’, consists on allocating larger balances to the central stations. It generates an increasing deterioration of the utilisation of the line as the ‘Inverted Bowl’ becomes deeper. As alternatives to bowl and inverted bowl dispositions of the mean processing times, Romero-Silva and Shaaban, (2018) analysed a monotone decreasing order, also called ‘Upstream Increasing’, which arranges the operators from the slowest to the fastest, and a monotone increasing order, ‘Downstream Increasing’, which disposes the workers from the fastest to the slowest. Results achieved on a 5-stations line showed that the upstream increasing configuration performs significantly better than balanced lines in relation to the average amount of jobs in the buffers. On the contrary, strongly worse performances are achieved by the downstream increasing disposition. Concerning the output rate, the two best patterns have been inverted bowl and upstream increasing, which generated performances comparable with the ones of a balanced line. Those outcomes are aligned with previous research on the part of Shaaban, McNamara, and Dmitriev (2017).

The Bumping Model
This new model takes the name of Baton Bumping Zone Balancing. This topic has been introduced and analysed by Charles Protzman in his “The Lean Practitioner’s Field Book”, written in 2016 with Fred Whiton, Joyce Kerpchar, Christopher Lewandowski, Steve Stenberg and Patrick Grounds. In this book, they describe the Baton Bumping Zone Balancing as one of the Proven, Practical, Profitable and Powerful Techniques for Making Lean Really Work.

It moves from the concept of station balancing to open up to work balancing. It allows to obtain One-Piece Balanced Synchronized Flow (OPBSF), for which it is necessary to change paradigms and systems that exist in sit-down station balanced lines and to be open minded enough to develop a new strategy. This approach means to set up the line to follow the flow of the product regardless of the times at each station. The buffers are eliminated and the workers are no more assigned to workstations, but to work zones across the workstations. The rule is that the worker must continue to build until the operator at the following station pulls the part from him. In this system, the operators or assemblers are spread out on the line to work just like runners in a relay race. Like the baton handoff in the relay race, when an operator completes a unit, he walks back to the previous operator and bump him by taking his part regardless the amount of work already realized on it by the previous operator. The bumped operator then goes and bumps the worker before him and so on until the first operator in line starts a new part. Since the Baton Bumping Zone Balancing has been introduced in the lean philosophy branch, its main benefit is the reduction of wastes. In particular, it diminishes the workers’ idle time and the WIP level in order to guarantee only the minimum amount necessary to keep the flow. Protzman (2016) provided a theoretical description of Baton Bumping Zone Balancing, while no simulations have been put in practice to assess the achievement of the expected results.
Methodology
In the methodology section, authors present job and shop characteristics of the simulation model, along with the features of the Bumping Model.

Shop floor and job characteristics
A simulation model of a pure flow shop has been implemented in Python using the SimPy module. We have kept our flow shop relatively small since this allows causal factors to be identified more easily.

Among the possible shop configurations, the Pure Flow Shop is the considered in this study. The reason behind this choice lies in the characteristics of the model under investigation, that is the Baton Bumping Zone Balancing. It performs better when the operators are arranged in an ordered manner, in particular with fastest person placed at the end of the line and the slowest at the beginning. Hence, to assure this condition, the flow must be directed. Moreover, another condition to successfully apply the Baton technique is to have a constant routing. All the jobs must visit all the workstations in their routing to be successfully completed, otherwise it may happen that an operator cannot take the piece of the operator upstream. If that occurs, the sequence of activities that is at the base of the theory fails and it becomes inapplicable.

It is assumed that all jobs are accepted, materials are available, and all necessary information, e.g. regarding shop floor routings and processing times, are known. If order release is applied, jobs are not immediately released to the shop floor, but retained in a so-called pre-shop pool (PSP) from where they are released to meet certain performance targets. As release rule, it is considered a periodic release, meaning that jobs are released from the PSP every 480 time units. The whole job and shop characteristics are presented in Table 1.

In the model, all the products have the same priority when queuing in the pool upstream of the next station; thus, all the products have the same characteristics and there are no product families. In order to better focus on the objectives of this study and not to...
influence the results, other factors of variation and uncertainty, such as products breakages, production of defective products, lack of capacity of the handling systems, were not considered.

The shop is designed to have five fixed stations, which perform a specific activity in the overall process. The work in process can be stacked in an input queue, which is placed upstream of the station. Five pools contain the work in process and the buffer does not have a finite capacity but can virtually store an infinite number of jobs. Figure 2 provides a better visualization about the logical arrangement of the shop floor elements.

The reason behind the choice of the number of station comes after the suggestions of different authors found in literature. Hillier and Boling (1967) demonstrated that a line with more than five stations shows performances improvements of few percentage points, basically not significant to justify a further shop floor extension.

![Figure 2 – Logical arrangement of Shop Floor elements](image)

**The Bumping Model**

The introduction of the Bumping Model has been introduced in the simulation model as a new worker’s arrangement rule to be tested. The computational model of the bumping rule strictly follows how it has been theorized by Protzman (2016). The workers, as soon as they are idle, can move to the machine upstream and take the work in process, then they go back to their station in order to continue the job. As described in Protzman (2016), workers are arranged in an ordered manner, with fastest worker placed at the end of the line and the slowest at the beginning.

The computational model performs the following steps:

1. The operator (e.g. W3) is working on a job. Two scenarios may happen:
   1.1. W3 finishes his job. Thus, he/she places the job in the pool of the machine downstream (S4);
   1.2. W4 takes the job from W3’s hands.

   In both cases, W3 is not working on a job.

2. W3 has to take the next job from his/her Pool 3.
   2.1. If there are jobs in its queue, operator W3 picks a job from there.
   2.2. If there are no jobs in W3 queue and W2 is working, W3 takes the part of W2.
   2.3. If there are no jobs in W3 queue and W2 is not working, W3 is idle until W2 gets a job.
The procedure is looped asynchronously and individually for each worker.

**Design of Experiments**
A full factorial design has been used. The levels and the factors tested have been presented in Table 2. To reduce the variance between experiments and to focus only on the variations due to the parameters of the simulation, the common random technique has been used. Therefore, for each replication of the same experiment, different sample of jobs are used, while, the same replication in the different experiments shares the same sample of customer’s jobs. The procedure used to compute the warm up period is the Welch method, presented in Mahajan (2004), and it has been performed for all performance measures. Results were collected over 4000 time units following a warm-up period of 2000 time units. To determine the number of runs, the Mean Squared Pure Error (MSPE) has been implemented for the performance measures used. The number of runs chosen, 100, is equal to the maximum that allows the convergence of the MSPE for all performance measures.

The four main system performance measures considered in this study are the following: Gross Throughput Time (GTT), the time between order entry and completion; Shop Floor Throughput Time (SFTT), the time between order release from the PSP and completion; Percentage of Tardy Orders, the percentage of orders with a positive lateness (given by the completion date minus the due date); and, Mean Tardiness, given by max(0;lateness).

**Conclusions**
This research paper is intended to be a methodological paper that proposes a simulation model through which benefits and impacts of the Bumping Model theorized by Protzman, (2016) could be investigated for the first time.

According to the literature, preliminary results show the advantages in terms of reduction of WIP and idle time.

In the literature, the first positive impact of Baton is the maximization of the efficiency of the team members. It is the result of cross-training and of the flexibility of the operators allowed to move and work on the different stations. Thus, this kind of balancing can be also seen as a driver for the cross training of the employees. In addition, the layout resulting from this configuration makes it easy for the workers to rotate, not only to different positions of the line, but also in and out the line. This continuous rotation and variation of the tasks to be performed has a positive impact also on the satisfaction of the operators, leading to an increase of the motivation with consequent reduction of the absenteeism. In relation to the performances of the line, the main advantage of the Bumping Model is the maximization of the output and the corresponding productivity obtained by using the fastest person to create the pull.

Abstract

This study focuses on the relations between supplier collaboration, sustainability, and market performance in the context of e-business. The data was collected with a cross-sectional random sampling of online store operators located in Finland. Structural equation modeling was used to test the hypotheses. The results did not promote the hypothesized direct link between supplier collaboration and market performance. Instead, supplier collaboration influences market performance via e-business sustainability.

Keywords: Supplier collaboration, E-business sustainability, Market performance

Introduction

The growth of e-business has resulted in major changes regarding how companies operate in the markets. Supplier collaboration has been specifically affected (Scuotto et al., 2017; Yang et al., 2017). E-business, defined as a concept that covers aspects relating to the selling of goods or services online, has enabled information sharing throughout the supply chain, which has made wider integration possible between supply chain members. Thus, supplier collaboration is seen as a way for organizations throughout the supply chain to distribute knowledge, network to enhance performance, and decrease total costs (Soylu et al., 2006). For this reason, the literature often refers to supplier collaboration as an essential facilitator of firm performance (Liu et al., 2009; Cao and Lumineau, 2015; Bals et al., 2018).

In addition, the rise of e-business has put the role of sustainability in the spotlight. In the context of e-business, it is often perceived that the traditional goal of firms, defined as providing profits for owners, has been complemented by more socially and environmentally sustainable goals (Klassen and Vachon, 2003; Oliveira and Martins, 2010; Blome et al., 2014; Al Omoush et al., 2018; Ukko et al., 2018). Concurrently, companies must focus on managing both internal and external relations to become more
socially and environmentally responsible, while retaining economic sustainability (Schrettle et al., 2014; Luzzini et al., 2015; Chen et al., 2017). Many scholars now acknowledge the significance of supplier collaboration in attaining sustainability in the business field (Soosay and Hyland, 2015; Chen et al., 2017). Comprehension of the influence of integrated sustainability and supplier collaboration on company performance is finite (Hollos et al., 2012; Blome et al., 2014). However, the influence of supplier collaboration on sustainability in the e-business context, as well as the impact of such commitment on performance, is empirically under-researched.

This study tests the relations between supplier collaboration, sustainability, and market performance, in the context of e-business, to address the illustrated gaps. In this study, we argue that supplier collaboration leads e-retailers to develop e-business sustainability and in turn, deliver enhanced market performance. Thus, the study contributes to research on sustainable supply chain management by investigating the relation between supplier collaboration, sustainability, and market performance in the context of e-business. The results offer implications for companies operating in e-business by supporting collaboration with suppliers and sustainability values while maintaining high market performance.

This paper begins with a theoretical background of supplier collaboration in the e-business domain. Next, the theoretical model is presented, and its hypotheses are discussed. The methodology adopted for the study is then explained, and the results are presented and discussed. Finally, contributions to research and managerial practice are proposed, accompanied by future research directions.

Theoretical model and hypotheses

Definition of key concepts

Supplier collaboration. Supplier collaboration refers to a critical business process for developing closer relationships with key suppliers to create relationship value (Autry and Golicic, 2010; Lambert and Schwieterman, 2012; Bals et al., 2018; Bals and Turkulainen, 2017). This process also demonstrates the importance of relational mechanisms in relationship activities (Jayaraman et al., 2013; Selviaridis and Norrman, 2014; Kreye et al., 2015). Relational mechanisms refer to the extent to which relationships are governed by social interactions, such as personal contacts, information sharing, mutual support, and teamwork (Jayaraman et al., 2013; Cao and Lumineau, 2015). Previous studies in operations and supply chain management identified exchanging information, joint sense-making, and integrating knowledge as important relationship mechanisms in the supplier collaboration (Selnes and Sallis, 2003; Cheung et al., 2010). Furthermore, collaboration between e-retailers and suppliers represents a critical component of service delivery processes, through which e-retailers have direct input in the development of e-services (Ngo and O’Cass, 2009).

E-business sustainability. Companies using e-business applications are more sensitive and responsive to their environment and more aware of the role of e-business applications in gaining sustainability and long-term competitiveness (Al Omoush et al., 2018). Many studies present the concept of sustainability in terms of environmental, economic, and social aspects (e.g., Pålsson et al., 2017; Rantala et al., 2018). In e-businesses, this concept may describe the extent to which the e-business application allows the company to operate in economically, socially, and environmentally sustainable ways. This definition is used as a definition of e-business sustainability in this study. When focusing on e-business sustainability from the economic perspective, the evolution of digital distribution
channels, such as software platforms, operating systems, web services or online shops (Nylén and Holmstrom, 2015), may increase the sales and market shares of the companies. From the social aspect of e-sustainability, e-service recovery is an example that can be defined as the process of electronically handling customer problems and turning them from a negative into a positive experience (Oliveira and Roth, 2012). On the other hand, in many parts of the world, an online store may be the only way to obtain a particular product or service and can, therefore, affect social sustainability. Regarding the environmental aspect of e-business, information richness that refers to the quality of information about environmental impacts presented in the e-business portal can be essential (cf. Oliveira and Roth, 2012).

**Hypothesis development**

The hypothesized model is demonstrated in Figure 1. The model indicates that supplier collaboration in managing the e-business provides the potential to increase market performance. However, our model suggests that such potential is realized only when attention is paid to e-business sustainability. While supplier collaboration is crucial in making the e-business work, sustainability engagement offers the channel through which suppliers and focal firms can enhance e-business sustainability and further provide the way for the focal firm for succeeding in the markets. Thus, a firm that embraces a lack of e-business sustainability may not necessarily attain enhanced market performance, even though their suppliers had “properly” informed them concerning e-business. Thus, the model proposes that e-business sustainability act as a mediating mechanism that connects supplier collaboration practices and market performance. Next, two hypotheses are developed.

![Figure 1 – Hypothesized model](image)

The position of the firms in the market resides in the firm’s competences, routines, and practices, which enable firms to perform more preferably in different marketing activities, including customer services, business brand, and sales promotion (Ho and Lu, 2015). Because development of firms’ competences is executed through learning procedures, there is a need for cumulative experiences and complementary resources, which are achieved with supplier collaboration (Ho and Lu, 2015; Mishra and Shah, 2009). Furthermore, research of supply chains has revealed that suppliers could learn much from service experiences created by suppliers and different practices (Cheung et al., 2010). Moreover, gaining external knowledge and higher firm performance can be achieved by the firms’ ability to leverage partners, including supplier collaboration (Gupta and Polonsky, 2014; Krause et al., 2007). Accordingly, supplier collaboration provides multiple benefits, such as new product development, operational performance, and
knowledge creation for the companies, which contributes to market performance (Cao and Zhang, 2011; Flynn et al., 2010; Mahmood et al., 2011).

In supplier collaboration, continued relationships, interactive activities, and working together help partners to deepen their understanding of restrictions, strengths, and enhancing opportunities for collaborative activities that result in improved customer services and offerings as well as market performance through quick responses (Cao and Zhang, 2011). Ho and Lu (2015) refer to supplier collaboration as a double-edged weapon that improves exploration and hinders exploitation of market performance. Ho and Lu (2015) noted that growth in firms’ performance, achieved by supplier collaboration, decreases companies’ willingness to enhance their internal resources, learning, and competences to improve marketing competences. Consequently, the effectiveness of exploitation to create customer value and enhance market performance will diminish. Based on the discussion above, the first hypothesis is formed as follows:

Hypothesis 1: Supplier collaboration is positively associated with market performance.

With the growing number of possibilities for product and service offerings, firms taking advantages of e-businesses today are growingly demanding sustainability engagement (Oláh et al., 2019; Aras and Crowther, 2009). As such, sustainability engagement has become more important to develop e-business operations that pay attention to economic, social, and environmental sustainability, not only to attract but, more importantly, to keep customers (e.g., Pålsson et al., 2017). The development and implementation of e-business sustainability will enable e-business operators to build long-lasting relationships with their customers and thus improve market performance. For example, the economic sustainability of e-business requires that firms should not only focus on short-term transactions and deliveries but also on long-term customer relationships. Firms should also ensure that customers can see value in their purchases and be satisfied with them (Oláh et al., 2019).

The social sustainability of e-business and its intersection with social media provides a wider audience through the rise of social commerce (Wang et al., 2019). By combining e-business with social media solutions as part of e-business operations, social commerce creates new ways to develop social sustainability, thus giving firms new mechanisms to develop customer channels for customers to improve their purchase decisions: for example, through interactions and user-generated content (Wang et al., 2019; Kim and Kim, 2018; Zhang et al., 2017). As such, social commerce provides solutions for firms to enhance the social sustainability of their e-business and increase their market performance through customer engagement (Zheng et al., 2015).

Many of the environmental harms in contemporary e-businesses are based on the transportation and logistics of delivered products and services. Thus, paying attention to logistics is an important part of environmental sustainability development. For example, Al Omoush et al. (2018) noted that manufacturing companies have a wide range of business partners, including suppliers, distributors, and logistics companies, that must share information concerning orders, production, inventory, and delivery of products and services. Sharing this information, from the aspect of environmental impacts on e-business platforms (e.g., online shops), may affect market performance. E-business platforms should be flexible and time-reliable, and both firms and their customers should be able to monitor processes to reduce carbon emissions by decreasing customer returns (Oláh et al., 2019; Yang et al., 2016).
Based on the considerations presented above, it can be said that e-business sustainability plays a crucial role in transforming supplier collaboration to gain higher market performance. As such, the second hypothesis is presented as follows:

Hypothesis 2: E-business sustainability mediates the relationship between supplier collaboration and market performance.

Research methodology

Data collection
Data were collected from a survey of companies located in Finland. The sample consisted of firms that have an online store. The respondents worked in management positions, which gave them good information when answering items related to online store operators’ supplier collaboration, e-business sustainability, and market performance. Initially, the survey was sent to 2,312 online store operators, which is about 31% of the total number of online stores in Finland. Of the 2,312 surveys sent, 109 responses were returned. Of the surveys returned, 75% had five or fewer employees, and 25% had more than five employees. About half of the online stores had been established for less than five years, and half were established more than five years ago. The survey results showed a diverse range of products, including clothing, athletics, decoration, construction, information technology, and management consulting.

Measures
Prior scales informed all of the scales used in the survey. A focus group formed by the researchers was used to identify a variety of supplier collaborations and e-business sustainability practices. These views were incorporated into the survey items presented below.

Supplier collaboration: A two-item scale ranging from 1 (“poor”) to 4 (“excellent”) was used to measure supplier collaboration. Respondents were asked to estimate their experiences with the services provided by the supplier and their relationship with the supplier.

E-business sustainability: We examined e-business sustainability utilizing a three-item scale, ranging from 1 (“poor”) to 4 (“excellent”). Respondents were asked about the extent to which their online store allows them to operate in an economically, socially, and environmentally sustainable way.

Market performance: Market outcomes were measured with a one-item, four-point scale, ranging from “totally disagree” to “totally agree.” Respondents were asked to estimate their firm’s position in the markets.

Control variables: Firm size (measured by number of employees), firm age (measured by the number of years since firm establishment), and competitive intensity (measured on a scale of 1 (“little competition”) to 3 (“lot of competition”) were controlled. Increased firm size and age may create better possibilities when competing in the markets. On the other hand, high competition may affect market performance by reducing the possibilities of competing in the markets.

Statistical analysis

Common method and non-response bias
Non-response bias was checked with an analysis of the variance test. Early respondents were compared with later respondents on several items (Armstrong and Overton, 1977).
The findings demonstrated no statistically significant differences in the variables between the two sets. Therefore, non-response bias did not exist. Utilizing only a single respondent from one company may pose puzzles relative to common method variance. This prospective puzzle was controlled via the Harman single-factor test (Podsakoff et al., 2003). Factor analysis results reveal that more than one factor emerged, and the prior factor did not explain the greatest portion of the variance. In survey design, clear and brief items, as well as different response forms, were used as recommended by Podsakoff et al. (2003). We also used a survey structure where the respondent could not identify exogenous and endogenous variables. The introductory letter assured the recipients that responses would be handled in confidentiality, and the respondents were encouraged to provide truthful responses. In sum, common method variance is not likely, due to the multiple remedies.

**Measurement model**

First, the data were tested to ensure unidimensionality, validity, and reliability. The item validation was made by confirmatory factor analysis (CFA) with the maximum likelihood method. Table I shows the loadings and error terms of the variables in relation to the corresponding factor. The values of the average variance extracted (AVE) were greater than 0.50, which is the suggested minimum (Hair et al., 2010) for convergent validity. Internal consistency was also supported since composite reliability (CR) measures were above the threshold of 0.70 (Fornell and Larcker, 1981). The results were also in favor of discriminant validity since the square root of the AVE (bold in Table 2) was higher than the correlations between factor pairs. In addition, reliability was checked with Cronbach’s α values (Nunnally, 1967), and the values exceeded the threshold. Since all the measures were supportive, the structural model test results are presented next.

**Testing of structural model and mediation**

The first model that tested a direct relationship between supplier collaboration and market performance demonstrated a poor fit. The results of the hypothesized model are demonstrated in Figure 2. Goodness-of-fit measures show a good fit: TLI = 0.950, CFI = 0.978, RMSEA = 0.077, and SRMR = 0.050. The path between supplier collaboration and e-business sustainability was significant (p ≤ 0.001) and strong (path coefficient = 0.55). Thus, supplier collaboration leads to an increased level of sustainability. E-business sustainability was also significantly (p ≤ 0.001) and strongly (path coefficient = 0.64).
related to market performance. Firm age was proven to have a significant (path coefficient = 0.27, \( p \leq 0.001 \)) effect on market performance, but firm size (path coefficient = -0.039, ns) or competitive intensity (path coefficient = -0.09, ns) were not significantly related to market performance. These results indicate that the relationship between supplier collaboration and market performance is mediated by e-business sustainability.

A competing model was tested to confirm this finding. A rival relationship linking supplier collaboration to market performance was tested in this model. The results reveal that a direct path from supplier collaboration to market performance is non-significant (path coefficient = 0.14, ns), whereas the paths between supplier collaboration and e-business sustainability (\( p \leq 0.001, \text{path coefficient} = 0.55 \)) and e-business sustainability and market performance (\( p \leq 0.001, \text{path coefficient} = 0.56 \)) were significant and strong.

Based on the above results, we found no support for hypothesis 1; thus, supplier collaboration is not directly associated with market performance. We found support for hypothesis 2, which means that e-business sustainability mediates the influence of supplier collaboration on market performance, as predicted.

**Figure 2 – Results for structural equation model**

**Conclusion**

This study tested the relations between supplier collaboration, sustainability, and market performance in the context of e-business. In terms of structural relationships, the results reveal significant backing for the hypothesized relations between supplier collaboration and e-business sustainability, and between e-business sustainability and market performance. Contrarily, the results did not promote the hypothesized direct link between supplier collaboration and market performance. These three findings suggest that the relation between supplier collaboration and market performance is fully mediated by e-business sustainability. Firm size and competitive intensity were not shown to affect market performance, but firm age was significantly related to market performance.

**Theoretical implications**

The study contributes to research concentrated on sustainable supply chain management as follows. First, the study diverges from previous research by investigating the relations between supplier collaboration, sustainability, and market performance in the context of e-business. The results provide clarification of the role of supplier collaboration as a fundamental enabling factor in determining the market performance of e-businesses. The results do not mean that supplier collaboration does not have an important value in improving market performance but point to the fact that its effect on market performance is realized through a commitment to sustainability. Second, through a survey of e-
retailers, the research empirically tests the implications of integrating sustainability commitment into supplier collaboration and provides a novel contribution to existing theoretical and conceptual studies.

Managerial implications
This study provides guidance for managers of the SMEs in the e-business context on how, with the support of e-business sustainability and supplier collaboration, to enhance market performance. Managers of SME’s in e-business context can scan for opportunities to enhance market performance while considering e-business sustainability in their business. Thus, while supplier collaboration is crucial in making the e-business work, its benefits are realized only when the online shop operator also pays attention to how it uses the online store in an environmentally, socially, and economically sustainable way. In addition, the results revealed that in the e-business context, companies with more experience could achieve higher market performance through e-business sustainability.

Limitations and future research
Certain limitations should be acknowledged in this study. The study was conducted in Finland, which might limit the generalization of our findings from Finland to other countries with different cultures in the e-business context. Also, the cross-sectional nature of the data may limit an in-depth understanding of how e-business sustainability mediates the relationship between supplier collaboration and market performance. Thus, further research with longitudinal data might help to enhance understanding of this topic.

Abstract

This work investigates integrating demand and shelf life data in inventory management systems at e-grocery providers. A store-based delivery setting, i.e., orders are delivered to consumers’ premises from regular brick and mortar stores, is considered. Consumer preferences and order patterns derived from an online survey and a conjoint analysis are loaded in a simulation and optimization-based decision support system to adjust pricing and replenishment strategies over time. Computational experiments focusing on the distribution of fresh milk highlight potentials of such integrated methods to facilitate a reduction in food waste within e-grocery operations.

Keywords: E-Grocery, Perishables, Food Waste

Background and Motivation

In a recent work on retail operations and food waste, Teller et al. (2018) highlight the importance of various business areas such as marketing, store and retail operations working closely together to facilitate sustainable processes. Among others, the authors identify interdependencies between retail store operations and consumer behavior as major obstacles for food waste reduction requiring future research. Consequently, a joint investigation considering both demand and supply specifics is required, however, related interdependencies are rarely studied in literature, particularly for e-grocery settings.

E-groceries, i.e., the delivery of food products ordered online to customers’ premises, is expecting high growth rates of 20% annually over the next years (IGD research, 2018).
Last-mile distribution of such grocery products, however, is challenging, particularly compared to traditional products ordered online such as fashion items, books and electronics. Regular market baskets are considerable larger, e.g., a single e-grocery order averages around 50 items in Germany and 70 ones in the United Kingdom (Wollenburg, 2018), and often consist of a variety of low-value items. Additionally, common characteristics of food logistics operations such as the perishability of products and their sensitivity to varying environmental conditions require special attention to deliver products to customers on time and in the desired quality (Fredriksson and Liljestrand, 2015).

Such e-groceries are often distributed through omni-channel retailing networks. This requires the simultaneous consideration of a wide range of interdependent decision factors such as picking strategies, delivery mode and time as well as the delivery area and how to handle returns (Hübner et al., 2016). The focus of this work is on inventory management strategies considering a store-based delivery concept. In such a setting, the e-grocery provider owns multiple brick and mortar stores and uses these locations to fulfill e-grocery orders. This allows the provider to enter the market swiftly at low investment costs and without requiring additional space, however, complicates inventory management systems as processes are predominantly optimized for regular store operations (Wollenburg et al., 2018).

To assist successful e-grocery operations, this work investigates integrating consumer preference data as well as various inventory replenishment and fulfillment strategies. A sample setting for highly perishable products is studied. It focuses on the option to dynamically adjust product prices and replenishment strategies based on current inventory levels to facilitate a reduction in food waste. The contribution of this work is threefold: (i) it introduces a consumer survey and a conjoint analysis to enable the modelling of individual preferences; (ii) develops a decision support system (DSS) to facilitate dynamic adjustments of product prices and fulfillment strategies; and (iii) derives managerial implications to support sustainable e-grocery operations in the future.

Related Work

Various authors study the reduction of food waste in retail operations and the development of last-mile distribution strategies for e-grocery providers. The majority of work focuses on either the supply or the demand side, i.e., on retail operations or consumer behavior respectively.

An overview of various last-mile fulfilment concepts operated by e-grocery providers is given in Hübner et al. (2016). Through a series of explorative interviews with various stakeholders and the analysis of key literature, the authors develop a strategic planning framework highlighting relevant decision factors as well as potentials and drawbacks of various fulfillment concepts. This work is further extended in Wollenburg et al. (2018) with a focus on the development of related logistics network over time. Revenue models in e-grocery operations and their environmental impacts are investigated in Belavina et al. (2017). A subscription model is compared with a per-order one through in-depth modeling of retail operations and consumer behavior. Results highlight positive impacts of a subscription business model as lower order sizes and more frequent orders result in less food waste at consumers and higher revenues for the retailer. Nevertheless, it further leads to higher delivery costs, indicating the importance of integrated approaches to consider various interdependencies present in e-grocery operations. The retailer’s inventory management system was not explicitly considered in this work and per-unit prices of groceries are not varied over time. Reiner et al. (2013) investigate that the design of in-store logistics processes such as store capacity management, lead-time, order period
and safety stock lead to higher on-shelf availability combined with reduced food waste. Price-dependent purchasing quantities under consideration of reservation price, another interesting stream of relevant literature, which is derived from revenue management, is addressed in Reiner et al. (2014). With a focus on order policies for perishable products, Haijema and Minner (2019) investigate the value of integrating remaining shelf lives of products on stock in replenishment strategies. By giving lower weights to products likely to expire soon and explicitly considering waste, the authors show that costs can substantially be reduced. Root causes for food waste within retail operations are identified in Teller et al. (2018) by conducting expert interviews and providing a process simulation. Beside inefficient replenishment strategies, demand variations and inefficient store operations, the authors particularly highlight the importance customer behaviour has on food waste. Consequently, to facilitate a reduction in food waste, a closer investigation of consumer related factors is required. Several studies have dealt with this issue and identified product quality (Wilson-Jeanselme and Reynolds, 2006), delivery fees (Waitz et al., 2018) as well as the travel distance to the store (Huang and Oppewal, 2006) as important factors. Apart from the identification of such factors, previous work also reveals that there exists heterogeneity among the individual customer preferences (Horta et al., 2017).

The importance of future research on revenue management in this area is highlighted in Agatz et al. (2008), who provide a review on e-fulfillment and multi-channel distribution. The authors note that, in contrast to traditional revenue management such as airline ticket operations where order costs are marginal, shipping expenses play a major role in e-fulfillment. Such expenses are significant and interdependent on other orders, which highly complicates revenue management activities. In Agatz et al. (2011, 2013), time slot management and related revenue management strategies are discussed. The focus is on offering different time windows for scheduled home deliveries at varying prices, while the delivered product quality is not considered. In e-grocery operations, however, incorporating such quality factors is of importance as it allows one to further diversify and potentially enables providers to reduce food waste while increasing revenues and customer satisfaction. In contrast to regular store operations where consumers pick specific items based on their preferences, in e-grocery operations, this decision is mainly performed by the provider, e.g., retail chain company, which has major implications on food waste and fulfillment costs (Fikar, 2018).

Little work on related decision support to facilitate sustainable food logistics is found in the literature. Jedermann et al. (2014) highlight the impact of different inventory policies on food losses. Six suggestions for strategic food supply chain management are given, including the selection of logistics providers and the number of hubs as well as transport mode choices. Furthermore, improvements in supply and demand management as well as diversification on quality are recommended. Fikar (2018) introduces a DSS enabling one to jointly investigate order picking and delivery strategies to reduce food waste in e-grocery operations. Results highlight a trade-off between minimizing delivery distances and minimizing food waste in delivery operations. A daily study horizon is modeled and replenishment strategies are not considered. Waitz et al. (2018) extend this work by incorporating consumer preferences and focusing on a multi-period problem setting. Therefore, each consumer is modeled within an agent-based simulation and initiated with individual preferences for service characteristics such as the width of time windows, shipping fees and delivered product quality. Varying service offers of the e-grocery provider are investigated to highlight trade-offs between service quality and logistics performance. Estrada-Moreno et al. (2019) considers the option to reallocate perishable products between various stores of a supermarket chain throughout a day of
operations. By developing a metaheuristics vehicle routing solution procedure, the authors show that such strategies can contribute to a major reduction in food waste.

**Method**

To support integrated demand and shelf life-based inventory management system, this work develops a model-driven DSS. Based on a consumer survey and choice-based conjoint analysis, consumer preferences are derived. Such preferences enable one to model customers individually within an agent-based simulation, which is facilitated to simulate various problem settings and derive managerial implications. Additionally, a special focus is set on replenishment strategies for perishable products to allow one an integrated view on e-grocery logistics operations. Figure 1 gives an overview of the various research methods and introduces the decisions considered in this work.

![Figure 1 – Integrating demand and shelf life data within e-grocery inventory systems](image)

The consumer data is collected for the Austrian grocery market. For the survey, 1,000 respondents have been recruited by a professional third-party panel provider and age, gender and residential area have been used to stratify the sample. The survey is containing questions regarding the general grocery shopping behavior as well as the respondents’ tendency towards online shopping. Additionally, a choice-based conjoint analysis has been included to identify the individual preferences for logistics services (delivery fee, delay of delivery, time-window width and delivery day) and milk specific characteristics (remaining shelf life and product price). Table 1 shows the included attributes and attribute levels. Figure 2 gives an impression of the choice-based conjoint tasks. Five such tasks have been randomly assigned to each respondent for which they have to choose between either picking one of the two products or the ‘none’ option. Based on these choices, the individual preferences of the respondents for the various attribute levels are derived by using the statistical software R (R, 2019), which allows the modelling of the existing heterogeneity across e-grocery shoppers.

Collected data is integrated within a simulation and optimization-based DSS to enable decision makers an integrated view of the various aspects influencing food waste within store-based e-grocery operations. The DSS, which is based on Fikar (2018), contains an agent-based simulation to model consumer behavior and integrates various heuristic solution procedures to optimize delivery and replenishment operations. Therefore, it considers an agent that applies the related replenishment method to set specialized strategies for perishable products. The basic replenishment setting assumes lost sales (no backorder of unsatisfied customer demand), a perfect supplier (i.e., deterministic lead-time) and a periodic base stock replenishment policy. This serves the basis to benchmark the extension of recently published policies for perishable products that may consider simultaneously pricing and related customer preferences. This enables one to demonstrate how pricing may influence consumer priorities to move to first-in-first-out (FIFO) instead of last-in-first-out (LIFO), potentially resulting in lower food waste for packaged products. Each consumer is modeled as an agent and acts according to his or her preferences. Additionally, collected order patterns and available time windows are used to generate demand. Figure 3 visualizes this ordering process of a customer agent within the DSS.
Based on the collected order frequencies, an event is generated within the DSS each time a customer agent is interested in purchasing e-groceries. Therefore, the agent is assumed to visit the webpage of the provider where an offer is presented stating both the guaranteed remaining shelf life of the product at delivery and its price. Various discounts can be offered to steer the consumer into buying products with shorter shelf lives, potentially enabling the provider to increase revenue and reduce food waste. To decide which offer is selected by the consumer, the utility of each offer is calculated by adding up derived preferences from the conjoint analysis for each of the investigated categories. The service offer scoring the highest utility is selected and subsequently ordered. If no offer scores higher than the non-choice options, no order is placed and the event is counted as a lost sale. Through the simulation of multiple weeks of operations and various problem settings and solution strategies, the DSS returns statistics on key figures such as revenue, food waste and inventory costs. This assists the decision maker to investigate benefits of integrating both demand and shelf life data within e-grocery operations.

Results and Discussion

To test the developed system, validate findings and derive managerial implications, a real-world based sample setting of a major e-grocery provider in Vienna, Austria is considered. The provider operates 255 stores throughout the city, which fulfill online orders of customers. Fresh milk, i.e., milk with an average shelf life of 6 to 10 days if refrigerated, acts as a sample setting for a highly perishable product. If stored longer, the product cannot be sold by the provider anymore and is recorded as a food waste within the study. The DSS is developed with AnyLogic 8.4 (AnyLogic, 2019) with all solution procedures coded in Java.

Preliminary results discuss the trade-off among various key figures based on simulated data as the consumer survey is still ongoing at the time of submission. Consumer behavior is shown to be of virtual importance to both reduce costs and food waste. If consumers employ a LIFO picking strategies, i.e., select products with long shelf lives first, a high amount of food waste occurs as older products cannot be sold before expiration. This requires either an adjustment in the replenishment strategy or results in substantial amounts of stock outs and lost sales. By adjusting pricing and steering customer to a FIFO selection, i.e., picking items with shorter shelf lives, costs and food waste can be substantially reduced. This trade-off between a reduction in costs due to lower food waste and changes in the revenue due to adjusted prices is of particular interest for future experiments conducted with real-world demand data. Additionally, guaranteeing the consumer a specific remaining shelf life of products at delivery has major implications on delivery operations, particularly when demand is high and only few products are
available. Delivery vehicles are highly utilized in such settings and may be required to travel additional detours to collect items with short remaining shelf lives located at distant stores, resulting in additional travel distances and potentially late deliveries. Such further impacts on delivery costs are shown to require special attention within the experiments to enable an integrated view of e-grocery operations and their impact on food waste.

Conclusions

This work introduced a framework on how to model the integration of demand and shelf life data within inventory management systems to facilitate a reduction in food waste. The focus is on store-based e-groceries and highly perishable products with fresh milk acting as the sample setting. To model demand, an online survey and a choice-based conjoint analysis is run in which customers are evaluating various service offers based on personal preferences. Derived order patterns and utilities both influence the replenishment strategies and delivery processes within a simulation and optimization-based DSS. First computational experiments with simulated data highlight various trade-offs of interest, particularly between logistics costs, revenues and food waste. Consequently, by integrating remaining shelf lives of products on stock within a DSS and facilitating collected consumer preferences to dynamically adjust pricing and replenishment strategies, decision makers can investigate various strategies to derive managerial implications and facilitate sustainable operations.

Future work focuses on integrating the collected consumer preferences within the DSS to develop strategies on how to use such data to enable flexible e-grocery operations. Therefore, a close consideration of current inventory stock levels and remaining shelf lives of products is required. Furthermore, investigating the impact of promotional activities and evaluating various adjustments of consumer behavior over time in response to the delivered service quality is of interest.

Middlesex University

Abstract

This study aims to explore how e-commerce companies utilize platform technology to build a business ecosystem. A multiple-case study is adopted and four successful county-level e-commerce companies are examined. Six main themes are identified as platform technology, internal and external factors, e-commerce strategy, managerial activities, economic outcome, and new business ecosystem. Through discussion from an adaptive structuration perspective, a conceptual framework associated with five sets of propositions is built. This study contributes to adaptive structuration theory through extending it to an inter-organizational focus in e-commerce context. The proposed framework provides potential guidelines for companies to implement their e-commerce business.

Keywords: E-commerce, business ecosystem, adaptive structuration perspective

Introduction

E-commerce industry has been growing dramatically worldwide and new e-commerce markets are continuously springing up. China, as the most fastest growing and largest e-commerce market, its e-commerce adoption in rural area is booming considering a large number of rural population of 589 million, accounting for 42.65 percent of the total population according to the National Bureau of Statistics report. Obviously, the domestic rural market is a large consumer group and stakeholder in China. Although there are ample articles that analyse the county level e-commerce in China in the point of view of economic development, government policy, driving factors and future forecasting, studies adopting e-commerce technology to build the business ecosystem are limited. Hence, in this research, we attempt to explore the following research question:

How do e-commerce companies utilize platform technology to build a business ecosystem?
To answer this question, we ground our research in Adaptive Structuration Theory (DeSanctis and Poole, 1994), which is the theoretical tool to explore how new structure occur through utilizing the advanced information technology (AIT) in action within and across organization (Rains and Bonito, 2017; Holweg and Pil, 2008; Lewis and Suchan, 2003).

The rest of the paper is structured as follow. Next section provides the literature review of e-commerce and business ecosystem, and the theoretical background of adaptive structuration theory; methodology section presents the case research method; findings and discussion section discusses the case findings against the reviewed literature and develops a conceptual framework and a number of propositions. Finally, this study is concluded through summarizing the contributions and limitations.

**Literature Review**

**Discussion on e-commerce and business ecosystem**

The essential element of e-commerce business is the platform. After “two-sided markets” theory came out, the platform has become an important research topic in different fields such as social networks, operating systems and transaction systems (Armstrong, 2006; Caillaud & Jullien, 2003; Roson, 2005). According to Evans and Schmalensee (2007), platform has a decisive role in ICT industry, distribution, finance, media and even urban planning. Cooke (2012) stated that platforms offer firms a significant potential for innovation.

Platforms are vitally important in creating value (Jacobides et al., 2006). Rochet and Tirole (2004) stated that platform strategy creates value through interacting with interconnected users in a two-sided market. Meanwhile, Evans et al. (2006) claimed that platform strategy is able to help strengthen platform with the network effect. Furthermore, Eisenmann et al. (2009) proposed that the adoption of suitable platform strategy enables firms take the lead in the market. In particular, Kim (2016) suggests that platform providers should consider quality management and revenue structure when building the business ecosystem in the two-sided market.

The study of business ecosystem focused on the interaction process among companies and the surrounding business environments. Moore (1993) suggested that all companies are as part of an ecosystem, and this economic community is established through a loosely interconnected network of actors including interacting organizations, individuals and other entities, cooperating, competing and coevolving their capabilities around an innovation, sharing knowledge, technologies, skills and resources to satisfy customer needs. Following the work of Moore, Iansiti and Levien (2004a) proposed that business ecosystems are formed through the interaction activities among entities in networks, including products or services providers, technology providers, outsourcing firms, a host of other organizations, distributors and suppliers. The ecological perspective does not view the economy as a machine but a living, evolving ecosystem (Rothschild, 2004). Various stakeholders of the ecosystem evolve and tend to align themselves (Gobble, 2014). Adner (2012) suggests a wide lens strategic tool for business managers seeking to assess, build or reshape business ecosystems.

**Adaptive structuration theory**

The theoretical lens adopted to investigate the research question is adaptive structuration theory (AST), which is first proposed by DeSanctis and Poole (1994) as a framework to examine the interplay between expected structures for behaviour that designers of IT systems has predicted or built into their systems and the structures that
actually emerge. It explains the outcomes of technology use in groups and organizations by focusing on the dynamic relationship between technology design and organizational practices (Rains and Bonito, 2017). Scholars argue that AST has been adopted largely at the intra-firm level, but it also a significantly useful theoretical framework that can help understand the relationship between technologies, the organizations who interpret them, and the new structure generated from the interpretation (Holweg and Pil, 2008; Lewis and Suchan, 2003; Ghoshal and Moran, 1996).

AST, in the original work of DeSanctis and Poole (1994), provides a model that describes the interplay between AIT, social structure, and human interaction to understand how technology structure can trigger organizational change. The model is investigated from three main segments that are AIT as social structure, group decision making in action, and new social structure. According to DeSanctis and Poole (1994), AIT offers social structure consisting of features and spirits. AIT features indicate the specific capabilities of a given technology and AIT spirits refer to the preferred set of actions and interpretations of technologies (Rains and Bonito, 2017), which represent the characteristics of AIT.

The action indicates the act of bringing the characteristics of AIT into specific decision-making activities through AIT appropriation (DeSanctis and Poole (1994). Rains and Bonito (2017) further adapt the action proposed by DeSanctis and Poole (1994) in the e-commerce context, and propose the e-commerce in action is the extend of use of web technology in facilitating e-commerce strategies and activities. E-commerce strategy is a consequence of structured behaviours to utilize the web technology in strategies for attracting new customers and creating new channel. E-commerce activity indicates the use of web technology for enabling customer-facing activities such as sales, market, service, distribution, etc. (Chatterjee and Sambamurthy, 1999; Chatterjee et al., 2002).

This research focuses on building the new e-commerce business ecosystem through the adoption of platform technology, which includes the investigation of platform technology, how companies utilize the platform technology in action, and the new business ecosystem established during this process. Thus AST is well positioned to explain the phenomenon and answer our research question.

**Methodology**

Interpretive case study was selected as a detailed research strategy, which includes interviews, archival records, documentation and field trips. According to Eisenhardt (1989), through analysing the context of a case study, the theory being studied can be illuminated. Yin (2009) states that a case study methodology is appropriate for investigating real-life context and contemporary events with the use of multiple data sources. Since this research aims to answer how e-commerce companies utilize platform technology to implement e-commerce towards building business ecosystems, the case study methodology would be valuable in providing explanations in an empirical and real-life context. Herriott and Firestone (1983) states that the multiple case design is more persuasive than the single case design and it can produce a more solid research. Hence, this study adopts multiple case methods and follows the corresponding processes recommended to conduct case study research and ensure the rigor.

After conducting an in-depth study of all the chosen companies, four typical cases are eventually selected in order to analyse and understand common issues in the county level e-commerce from the AST perspective. The four case companies represent the pioneers and the most successful cases of China's county level e-commerce, and the Chinese government awards them as the national exemplars of county level e-
commerce. County level e-commerce service providers can be categorized either by private platform operators or public-service-based platform operators. The four case companies selected are identified as the latter type that cooperates with the government and serves a large population of given areas. The basic information of the four case companies is profiled in Table 1.

Notes: The slash (/) symbolizes inexistence of corresponding business.

The data is collected between June 2016 and August 2018. Semi-structured interviews are conducted as the primary data source. 23 qualified interviews of the four case companies are selected out of 32 interviews conducted. The researchers visit the sites of all four companies and key stakeholders. To triangulate the information, archival data are also collected from company websites, news, internal company documents, and public reports. After data collection, data are coded and analysed. We analyse the data following an iterative process, carrying out a within-case analysis and a cross-case analysis successively. On many occasions we consult the interviewees and archival information in case of ambiguity. To illustrate the overall coding process, a data structure is provided in Figure 1.

---

1 It also represents the number of county level operation center.
2 It includes all the service stations in township, town and village.
Findings and Discussion

Six main themes are identified from the within- and cross-case analysis as platform technology, internal and external factors, e-commerce strategy, managerial activities, economic outcome, and new business ecosystem. After discussing and further making sense of the findings through comparing them with the literature, a conceptual framework is proposed with five sets of propositions to answer the research question (see Figure 2).
Interplay between input sources and e-commerce in action

We found that an interacting relationship between the characteristics of platform technology and e-commerce in action. According to DeSanctis and Poole (1994), AIT brings social structures (features and spirit) that enable or constrain social interaction. The platform technology of the case companies consists of mobile platform (Wechat) and web platform. Comparing to traditional computer systems that supports accomplishment of business transactions and discrete work tasks, such as billing, inventory management, financial analysis, etc. (DeSanctis and Poole, 1994), the capabilities (features) offered by Wechat and Web platforms are far beyond. In addition to above activities, they can further support coordination and interaction among actors who use these platforms and provide procedures for accomplishing the information exchange. The utilization of these platform technologies enables the case companies to open uplink channel meeting the needs of city, and to build the downlink channel serving the villages.

Meanwhile, the uplink and downlink channels further create new characteristics for the platform technology. For instance, in the uplink channel, three main segments are generated as sales, marketing, and supply chain service. One way of the sales is operating through social commerce, which indicates the additional sharing and spreading actions on Wechat to facilitate the sales of the uplink platform. In contrast with the initial capabilities of platform technology, the utilization of platform technology further creates new preferred set of actions and interpretations (spirit) of the mobile platform (Wechat) and web platform. This supports the study of DeSanctis and Poole (1994) that suggests the output of technology adoption emerges as the new source of structure. Combining these two aspects, thus, we propose that:

\[ P1. \text{ Platform technology enables the uplink and downlink channel in e-commerce strategy; and the development of strategy, in turn, creates additional sources of platform technology.} \]

Furthermore, we also identified four moderators that influence the interplay between platform technology and e-commerce strategy. Based on the internal and external factors analysis, we found that Ganjie performed best in entrepreneurs experience, innovation orientation, coordination, and political ties. This influence the utilization of platform technology in building the uplink and downlink channel. Ganjie sets up the most comprehensive segments in both uplink and downlink channels. In contrast, Minyu indicates the lowest level in terms of the four factors, and is able to establish the least segments in uplink and downlink channel. Meanwhile, the outputs of utilization of platform technology also vary depending on these factors. For example, when the outputs of generated from Ganjie uplink channel as the information from sales, marketing, and supply chain service segments, it requires the coordination among Ganjie internal teams to translate these information into the new characteristics of the mobile and web platform. Our findings do not support the direct relationship between group internal system and AIT appropriation proposed by DeSanctis and Poole (1994), and extend the study of Chatterjee et al. (2002) that indicates the positive influence of top management and coordination on web technology assimilation. Therefore, we propose our second set of propositions below:

\[ P2. \text{ The interplay between platform technology and e-commerce strategy varies depending on internal and external factors.} \]

\[ P2a. \text{ The richer entrepreneurs experience in e-commerce, the greater interplay between platform technology and e-commerce strategy will be facilitated.} \]

\[ P2b. \text{ The higher level of innovation orientation, the greater interplay between platform technology and e-commerce strategy will be facilitated.} \]
P2c. The better coordination among intra-organizational teams, the greater interplay between platform technology and e-commerce strategy will be facilitated.

P2d. The stronger political ties with local government, the greater interplay between platform technology and e-commerce strategy will be facilitated.

E-commerce in action
According to Chatterjee et al. (2002), the utilization of platform technology facilitates e-commerce strategy and activities. We found that all case companies, enabled by their mobile platforms and web platforms, build up the uplink channel and downlink channel as the overall strategies. The uplink channel facilitates three segments as sales, marketing and supply chain service; and logistics system, local service and service station are generated from the downlink channel. We further identified two categories of managerial activities from these segments, i.e., supply chain management and platform management (Johnson and Whang, 2002; Iansiti and Levien, 2004b; Kim, 2016). Regarding supply chain management, we found that Ganjie and All City perform better than Wenyuan and Minyu in both logistics management and information management. In respect to platform management, Ganjie and Wenyuan perform better than All City and Minyu in terms of quality management and marketing service.

This also supports similar argument by DeSanctis and Poole’s (1994) that indicates the AIT appropriation in strategy can be evidenced in the group decision-making activities. But extending it to e-commerce context, the managerial activities are categorized into supply chain management and platform management with each category further consisting of two sub dimensions. Through examining each sub dimension, the performances of different e-commerce companies can be realized. Therefore, we propose our third set of propositions:

P3. E-commerce strategy enabled by platform technology leads to various managerial activities that can be categorized into supply chain management and platform management.

P3a. Supply chain management of platform-based e-commerce can be conducted through focusing on logistics management and information management.

P3b. Platform management of platform-based e-commerce can be carried out through focusing on marketing service and quality management.

Outcomes of e-commerce in action
We identified two revenue structures of the case companies, the demand side and supply side. Through the uplink and downlink channels, and supply chain management and platform management, all case companies can generate revenue from demand side and supply side given the established platforms. This supports the proposition of Rains and Bonito (2017) and DeSanctis and Poole (1994) that the desired outcomes of the utilization of technology can occur when ideal appropriation occur and decision making activities match the task. Here, we further identify the ideal appropriation in e-commerce context is the uplink and downlink channel. Thus, we propose our fourth set of propositions below:

P4. E-commerce in action including both e-commerce strategy and managerial activity can generate revenue as the economic outcome.

P4a. Uplink channel strategy associated with managerial activity generates the revenue from the demand side.

P4b. Downlink channel strategy associated with the managerial activity generates the revenue from the supply side.
Interplay between E-commerce in Action and New Structure

We finally identified an innovative business ecosystem as the development of the case companies, which consists of three main components (Moore, 1993) and six sub sectors (Heikkilä and Kuivaniemi, 2012). This innovative ecosystem indicates technological change from Wechat to innovation technology, which also supports the similar argument by DeSanctis and Poole’s (1994) that the technology structure will be produced and reproduced during its adoption in group interaction. Their study grounds in group decision-making process in an organization, but e-commerce actions are more related to the interacting among organizations.

Considering the inter-organizational interaction of e-commerce, in addition to technology change, the innovative ecosystem of case companies also indicates collaboration with diverse stakeholders like research institute, information system, competition with other e-commerce companies, cooperation with local community and government, etc. Various types of actors and sources continually evolved during the process of the case companies operating e-commerce in actions. From core business to extended enterprise to innovation ecosystem, the case companies may change the ecosystem intentionally, such as All City expands the sales channel, or unintentionally, such as the ecosystem attracts research institute and universities.

Once the innovative ecosystem emerges, it serves as the new structure for case companies and provides them additional structure sources for operating e-commerce, such as technology, other actors, and environment. Therefore, in e-commerce context, we extend the proposition by DeSanctis and Poole’s (1994) through further considering a diverse group of actors and sources, and propose our fifth set of propositions:

P5a. New structure emerges as the characteristics of various sources and actors are produced and reproduced in e-commerce in actions over time. The sources and actors include platform technology, politics, social environment, and stakeholders.

P5b. Through producing and reproducing characteristics of sources and actors, new structure evolves both intentionally and unintentionally from core business to extended enterprises, and then to innovation ecosystem, finally, a business ecosystem can be formed.

Conclusion

This multiple case study aims at analysing the county-level e-commerce companies on how they utilize e-commerce technology to establish the innovative business ecosystem. We ground the investigation in adaptive structuration theory, and propose a conceptual framework associated with five sets of propositions to answer the question. By answering this question, several important theoretical and managerial contributions could be drawn.

First, this study identified six themes of e-commerce as e-commerce AIT, internal and external factors, e-commerce strategy, managerial activities, outcomes, and new business ecosystem. The conceptual framework proposed reveals various relationships among these themes. In particular, four moderators are identified that facilitates the interplay between e-commerce AIT and actions, i.e., entrepreneurs experience, innovation orientation, coordination, and political ties. The conceptual framework contributes both for academia and practitioners. Second, this study may be the first to explore e-commerce from an AST perspective. The AST perspective is proven as a useful tool to analyse the theme and building a theory of e-commerce business. Therefore, we contribute to the AST by applying it to an e-commerce context.

There are some limitations of this paper. As many county level e-commerce companies are disorientated in how to continue their businesses, this study lucubrates
the development pattern of four successful county level e-commerce companies. More cases may be required to further illustrate and refine this conceptual framework.

Abstract

Demonetisation occurred in India in 2016 and impacted the population by restricting access to cash. To understand how people were impacted tweets were used. Advanced sentiment mining techniques were applied to understand key positives and negatives about the implementation of demonetisation. The proposed approach for analysis differs from prior papers by focusing on the farming sector which is pivotal to Indian economy. Through demonstrating value added through social media modelling this paper provides a technique for policy makers to utilise social media data to adapt future policy changes more effectively.

Keywords: Digital economy, social media analysis, agriculture sector

Introduction

The Indian Government announced demonetisation of India's 500 and 1000-rupee notes, which made up 86 percent of the country's currency on 8th November 2016 (BBC News 2016). The intention of this drive was to address tax evasion, eliminate black money and promote a cashless economy. Agriculture sector, which contributes 23% of the GDP and employed around 59% of the Indian workforce (World Travel and Tourism Council 2018), saw severe impact on the individuals working in the industry as well as consumers, which ultimately affected the Indian economy. Specifically the majority of farmers depend on
cooperative banks for their loans to finance their day-to-day activities, which were not functioning following the demonetisation announcement. Social media platforms such as Twitter was flooded with the public feedback/opinions post demonetisation. Analysing social media data quickly and reliably to inform government on major issues faced by the sector can be critical to the success of such policy measures. The paper utilises the social media data from Twitter, collected during the demonetisation period to understand the impact of this disruption on the farming operations.

**Literature Review**

Previous research efforts in the area used social media dataset to understand the impact of demonetisation in India (Gupta et al. 2017, Singh et al. 2017, Vaid et al. 2017). These studies tried to analyse how social media behaved post demonetisation by twitter data from all the sectors without focusing on any specific one. The results from these analyses provided a general overview of the public sentiment but failed to highlight specific government operational implementation issues during demonetisation operation. Therefore, this paper focuses on studying the impact of demonetisation on the agriculture sector specifically by identifying specific government policy and operational considerations. Modelling methodology from the aforementioned papers are summarized in table 1.

<table>

Gupta et al. (2017) analysed sentiments of social media data arising from different regions of India in response to demonetisation. First they classified tweets into positive, negative and neutral using emoticons such as ‘:)’ and then included hashtags to represent views for trending hashtags such as ‘#ModiFightsCorruption’ to further identify sentiment of the tweet. After developing view on whether the tweets with emoticons or trending hashtags were positive, negative or neutral, they applied a naïve Bayes and SVM model to develop a model to predict the value for tweets that couldn’t be labelled. The analysis was limited to frequency and visualization considerations.

Singh et al. (2017) use the Valence Aware Dictionary for sEntiment Reasoning (VADER) approach to get positive, neutral and negative sentiment values for tweets. Typically positive and negative scores would be associated with 1 and -1, the VADER approach was used by Singh et al. (2017) because it assigns a more granular score. For example a score of 0.5 would be more positive than a score of 0.2. In addition to sentiment analysis they consider how to predict the most popular retweets using unigrams and bigrams through support vector machine (SVM), decision tree, logistic regression, multinomial naïve Bayes, random forest, Bernoulli naïve Bayes and K nearest neighbours. They do not use insights from VADER to support popularity of retweet analysis.

Vaid et al. (2017) used a naïve Bayes model to classify emotion and polarity based on a lexicon sample dataset and also utilise word clouds to suggest that sentiment towards
demonetisation has changed from November 2016 to March 2017. Their approach was focused more so on visualisation of frequencies of different emotion and polarities and representing the word clouds over two dates. It showed the time sensitive nature of perceptions towards tweets and the idea of using emotions to represent tweet content. Vaid et al. (2017) focused on visualization and word clouds over two dates.

The notable research gap is current papers on demonetization have not considered the operational management perspective of how to implement a change of this magnitude more effectively going forward. Additionally the other papers have not focused on the farming industry specifically, which is of primary concern in an agriculture dependent economy like India where 59% the Indian workforce is employed (World Travel and Tourism Council 2018).

Methodological Approach

A methodology is developed to analyse Twitter dataset through the innovative combination of bigrams (two word combinations) as well as emotions-based opinion analysis. The analysis uses social media data from Twitter to better understand the reaction of the Indian public towards demonetisation and its impact on the agriculture sector. The data comprises of tweets containing #demonetisation between 8th November 2016 and 2nd January 2017. The analysis of the data involved three main steps (i) data cleaning, (ii) feature selection using word combinations and emotion identifiers and (iii) opinion mining through support vector machine (SVM). When using the proposed methodology, the prediction model was able to achieve more than 74% accuracies for negative opinion tweets. Using this model, we classified the social media data into positive and negative set (depending opinions indicated in the tweets).

I. Data Cleaning
The data was pulled through the Twitter API and was in a text format. A number of steps were involved in the data cleaning stage in order to allow for ease in bigram analysis. In literature, we found that bigrams play a key role in training SVM and therefore proper data cleaning will ensure more interpretable results and higher predictive performances. Through the use of Natural Language Processing (NLP), the data was pre-processed by removing URLs, punctuation and numbers with the intention to only keeping words, retweets (RT), any @ symbol targeted individuals, hashtags and stop words. Furthermore the tweets consisted of English and other languages. However, we simply considered English tweets for analyses.

II. Feature Selection
Sentiment analysis was performed on the data through two steps. The first was to understand the emotions behind tweets and this involved looking up the words used within tweets against the National Research Council (NRC) Emotion Lexicon (Mohammad and Turney 2010; Mohammad and Turney 2013). The lexicon divides emotions into anger, anticipation, disgust, fear, joy, sadness, surprise and trust. One limitation is that the lexicon based approach does not consider negating words (Jia et al. 2009), for example ‘not happy’ would have a significantly different meaning to ‘happy’ without any preceding words. To account for this, we have used an approach proposed in Rinker (2018) where the sentiment mining procedure takes preceding words and modifies sentiment accordingly depending on if the word is considered a negator, amplifier, de-amplifier or an adversative conjunction and assigns a score. Note that that emotions are represented by the number of emotive words used in a tweet and positive/negative
sentiment is assigned a score.

Another step in the proposed analysis is to develop bigrams. It is possible to use more than two words however this has not been considered due to the limited sample size. For example the frequency of three words together reduces as sample size decreases since there are less words being examined. These bigrams are useful features to be included into the SVM model from the perspective of interpretability and better fit while considering the limitation of relatively small sample of 16,120 tweets. When identifying the bigrams, the main consideration was how frequently it occur in the tweets. This was achieved by counting all available bigrams from the sample dataset.

Additionally, the two word combinations were considered in the context of each tweet. For each tweet all pairwise combinations were filtered to see which words frequently occur together. Following this, these words were then checked for pairwise correlation and the higher correlation values were kept. Intuitively this means understanding whether or not pairs of words occur concurrently in the dataset. Unlike considering the frequency of bigrams, it is possible to capture general trends in the tweets. Another differentiating factor of this analysis from the bigram frequency is the words do not have directional impact since it involves correlation.

III. SVM Classification

By developing features it is possible to develop a SVM model to classify tweets into positive, neutral or negative towards the demonetisation with respect to the agricultural sector. The sample size is 4031. In order to train SVM, 1000 of these tweets were manually labelled for being either positive, neutral or negative towards demonetisation. We divided the dataset into two sets – training (75%) and testing (25%). After testing the model after training on 25% of the sample, we used it for classifying entire 4031 tweets.

As the tweets can be classified into positive, neutral or negative class. Each outcome class was modelled separately. This leads to three different binary classification models each for positive, negative and neutral class. The final class label was assigned based on the maximum probability of the three models. This is also known as the one-vs-rest methodology (Hsu and Lin 2002).

The features used for training the SVM model are the emotions identified through National Research Council (NRC) Emotion Lexicon (Mohammad and Turney 2010; Mohammad and Turney 2013), the positive and negative sentiment scores, the most frequently occurring bigrams and the most highly correlated two word combinations. The emotion and sentiment values are scaled and centred while the frequently occurring bigrams and two word combinations are treated as binary feature representing whether or not they occurred within each tweet.

One of the issues with the data is it is unbalanced with much more negative sentiment tweets than neutral or positive sentiment tweets. To solve for this issue to ensure the SVM fits well (while avoiding overfitting and biases), the Random Over-Sampling Example (ROSE) technique was applied (Mernadi and Torelli 2014). ROSE uses bootstrapping to generate a more balanced dataset based on the less frequent variable value. Once the balanced dataset was developed, a radial SVM approach was applied to train the model. SVM was applied since it has been successfully used in literature (Singh et al. 2017, Gupta et al. 2017).

Results and discussion

When analysing tweets classified with negative opinions (negative set) through word combination network diagrams (see Figure 1), following main operational issues were
A. farmers or small traders were not able to use digital platform for payments/transactions and resulted in lenders exploiting farmers.
B. due to cashless scenario post demonetisation, farmers were unable to buy seeds in the sowing season, feed for livestock and to hire labour, which resulted in increased food prices. This was mainly because seed sellers were not willing to accept old notes.

Similarly, in case of positive set shown in Figure 2, following steps of the government were supported:
A. some tweets supported government’s step towards helping farmers by allowing them to use old currency notes

Overall, based on opinion analysis, the impact of demonetisation on agriculture sector was significant as there were more than 80% negatively classified data in the whole dataset collected. There were little positives other than when demonetisation policy was eased for farmers for few days.
An SVM approach was applied to better understand drivers behind positive and negative sentiments for demonetisation. The model was trained on hand labelled tweets and this methodology allows for non-labelled tweets to be assigned to a predicted class label. Therefore, there were 4031 tweets on demonetisation within the agriculture industry, 1000 of these were manually labelled and the other 3031 tweets were labelled using trained SVM. The SVM model trained used the bigrams suggested earlier as well as emotions as features. The validation statistics for each individual model classes are presented in Table 2.

<table>

</tr>
<tr>
<td></td>
<td>81.6</td>
<td>79.2</td>
</tr>
</tbody>
</table>

The Cross-Validation (CV) was partitioned to be performed on 75% of the manually labelled data, while the other 25% was kept out to test performance. Notably, the models provide an acceptable level of Gini and Accuracy for the sample size used and are consistent across CV and Test stages. After aggregating the three models into a single outcome class label identifying if a tweet is negative, positive or neutral, the overall performance of the model is 69% when emotion is included. This shows a significant increase from the 57% when emotion is not incorporated while training the SVM model.

For the SVM approach variable importance was compared, and outside of emotion the most common phrases to influence negative, neutral and positive views is captured in Table 3.

<table>
<thead>
<tr>
<th>Key phrases excluding emotion</th>
<th>Positive</th>
<th>Neutral</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Real estate”: Increase in real estate values as black money potentially gets funnelled there</td>
<td>“Crop loans”: Loans are required in order to purchase crops. “India farmers”: News articles discussing those that were effected.</td>
<td>“Hurt farmers”: Describing that farmers have been hurt by what was perceived as poor policy implementation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Key emotions in order of importance</th>
<th>Positive</th>
<th>Neutral</th>
<th>Negative</th>
</tr>
</thead>
<tbody>

<td>Anger</td>
<td></td>
</tr>
<tr>
<td>Anticipation</td>
<td>Trust</td>
<td>Sadness</td>
<td></td>
</tr>
<tr>
<td>Surprise</td>
<td>Sadness</td>
<td>Fear</td>
<td></td>
</tr>
</tbody>
</table>

In particular emotions are consistent across different dependent variables such as anger appearing in both positive and negative tweets. The reason for this is that while Table 3 captures importance of the variable it doesn’t capture directional impact. To represent this Table 4 performs a logistic stepwise regression which shows what type of influence the
variable has, with positive coefficient corresponding to a supporting argument for the given classification.

Table 4 – Emotion Directional Impact within Logistic Stepwise Regression

<table>
<thead>
<tr>
<th>Classification</th>
<th>+’ve sign coefficient</th>
<th>-’ve sign coefficient</th>

<td>fear, trust, anticipation, sadness, anger</td>
</tr>
<tr>
<td>Neutral</td>
<td>surprise</td>
<td>Anger</td>
</tr>
<tr>
<td>Positive</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In Table 4 anger is shown to be more likely to appear in negative comments, and less likely to occur in positive comments. Any emotions shown are less likely to make the comment neutral. Additionally surprise seems to be the most common emotion represented in positive comments.

This methodology can be further applied out of sample to label the 3031 tweets that were not manually labelled. An example of this is shown in Table 5.

Table 5 – Out of Sample Most Intense Perceptions towards Demonetisation

<table>
<thead>
<tr>
<th>Raw text</th>
</tr>
</thead>
<tbody>
<tr>
<td>Negative</td>
</tr>
<tr>
<td>RT @subyroy: Collapse of transport, trade, agriculture, employment, caused by deliberate monetary error #DeMonetisation #ModiJai</td>

</tr>
<tr>
<td>Positive</td>
</tr>
<tr>
<td>Don’t worry about cash! Shop cashless with amazing discounts and cash back offers. #currencyban #DeMonetisation...</td>
</tr>
</tbody>
</table>

The tweets shown in Table 5 have the highest probability of being negative, neutral or positive respectively. Notably the example tweets in Table 5 capture the general view of the tweets that were manually checked. Negative perceptions towards demonetisation tended towards issues with money being available and its impact on farmers. They suggested that the lower class was being harmed and there was no impact on actually removing black money. The neutral perceptions towards demonetisation were more concerned with stats and figures, for example announcing a news broadcast. The positive perceptions towards demonetisation were about considering the long run, it also shows why features such as fear would appear in the variable importance plot and indicates the shortcomings of not including negation.

Conclusion

Based on the proposed analytical methodology utilising emotions, it was able to accurately classify social media data into positive and negative sentiments, which was later used for identifying issues with the Government’s implementation of demonetisation drive across India. Network diagrams were applied to identify the word combinations/bigrams which revealed better understanding/summary of the information contained in the social media datasets.

The results identified key concerns about demonetisation relating to sowing season, difficulty in purchasing seeds and interaction with banking. The model also implies that anger, anticipation and sadness were the most informative emotions within the tweets.
This information can be utilised to understand key concerns of those that are related to how the government can better manage key concerns and emotions related to demonetisation.

The proposed methodology can be applied in other areas such as consumer online feedback analysis for improving product features and related operations. The advantage of this type of analysis is it is possible to automate the analysis process of textual information in big data era. This research could be applied to any government policy changes for e.g. impact of Brexit on various industrial sectors. Nevertheless, to derive the full benefits, this approach should be implemented on a suitable software platform in which all the methodology components of the text analytics can be integrated holistically.

Abstract

This paper studies the influence of accessible information and communication in distributed control systems for Industry 4.0 applications. To this end, we compare a purely decentralized and a hybrid heuristic in a multi-agent system in order to solve graph colouring dynamics. By means of simulations, both heuristics are compared, and while no heuristic clearly dominates the other, insights on design challenges in distributed control are derived.

Keywords: Graph Colouring Dynamics, Distributed Control, Scheduling

Introduction

The future of digitalized and networked manufacturing systems is currently envisioned under a multitude of names, such as Industry 4.0, Manufacturing 2.0, Internet of Things, and many others. They share the vision of distributing tasks of production control to ‘intelligent’ machines, parts and products in order to attain higher flexibility, adaptability, counteracting increasingly complex and dynamic environmental conditions, and thus yielding higher logistic performance. The envisioned gain however, comes at a cost: With system behavior left to selfish actors, both the stability and the quality of the attained solution can deteriorate. The apparent trade-off has lead researchers to believe that a combination of centralized and distributed control may lead to improved logistic performance by the interplay of local and global decision-making. Moreover, it has been stated that the performance gain from a combination of centralized and distributed decision strategies increases with higher levels of decision task complexity (Scholz-Reiter et al., 2009). When implementing such a system in production in light of Industry 4.0, intelligent objects and distributed control create a new trade-off situation in production system design. Such trade-offs include new problems, such as deadlocks due to selfish actors (Thomas et al., 2012). During the design stage, a certain degree and form of combination between centralized and distributed control has to be determined. Therefore, the designer has to accept a certain
degree of myopic decision-making in exchange for positive, emergent system characteristics, such as higher adaptability, quicker response, etc. (Bendul & Blunck, 2018). However, the optimal degree of distributed control in a hybrid decision strategy remains an open question thus far. In the interest of approaching such a hybrid decision strategy, we aim to answer the following research question:
Which insights can be gained through a comparison of a purely decentralized approach and a hybrid approach, utilizing a broker of global information?

In production planning, Multi Agent Systems (MAS) are a common tool for modeling the usage of decentralized control. We use a minimal model based on Graph Coloring Dynamics in conjunction with MAS to study how communication and information flow structure affects the performance of decision strategy. By means of simulation, we compare a purely decentralized decision system with a hybrid decision system, which allows agents to access global information through a central information broker.

The rest of the paper is structured as follows: The next sections gives a briefly refers to literature in connected research streams, followed by a description of the applied methods in section 3. In section 4 the findings are presented, followed up by the conclusion in section 5, which discusses theoretical and practical contributions.

**State of the Art**
The fourth industrial revolution, commonly referred to as Industry 4.0, describes the technological impact of connected production systems. Expectations of the impact of Industry 4.0 include among others new levels of visibility, transparency, adaptability and better forecasting throughout industrial production (Lasi et al., 2014). This vision of production is characterized by so-called Cyber Physical Systems (CPS) (Monostori, 2014; Jazdi, 2014). Such systems exhibit a level of connectivity that allows communication with humans as well as with other CPS. In theory, embedding a multitude of CPS into a production network, such setup would allow for machines to act with regard to other, i.e., a CPS could tolerate a downside in its own productivity for the sake of increasing the entire systems productivity. This appealing vision however raises the question of coordination (Panetto et al., 2019; Olfati-Saber et al., 2007). Distributed control promises advantages over conventional concept such as improved agility (Trentesaux, 2009). Such distributed control concepts are also deployed in holonic production systems (Brennan, 2001). The common approach to realize such distributed control is the use of MAS. In these systems, so-called agents are deployed at every point in the distributed system where a decision can be made. Leitão (2008) gives an overview on the use of agent-based decision systems in manufacturing control. In the context of Industry 4.0, such agent-based decision systems are seen the proper tool to realize the vision of a more efficient, flexible and agile production systems (Whitbrook et al., 2018; Zhang et al., 2017; Barbosa et al. 2018, Shujka et al., 2018, Shukla et al., 2018). Furthermore, such approaches of distributed control allow a new level of adaptability in the manufacturing process (Kim et al., 2019). In literature, different configurations of distributed control concerning the degree of distributed control have been proposed (Monostori et al., 2015; Kozjek et al., 2018). The question for the optimal degree of decentralized in such hybrid decision systems however, has not been answered thus far. Blunck et al. (2018) studied the impact of elevated agents that assume a leader role due to having a greater connectivity in comparison to regular agents, and thus assessed one approach to determine an optimal degree of decentralization. This paper tries to gain further insights from the comparison of a purely decentralized approach and a hybrid approach, utilizing a broker of global information.
**Methodology**

We use a minimal model based on Graph Coloring Dynamics, as this model has been shown to be feasible in order to model Production Planning and Control (Blunck, 2018). In Graph Coloring Dynamics a given graph $G:=(V,E)$, defined by its vertex set $V$ and edge set $E$, requires a coloring $C = \{c_1, \ldots, c_{|V|}\}$ such that every pair of vertices that are adjacent have different colors (i.e. $n,m \in V$, $(n,m) \in E \Rightarrow c_n \neq c_m$). The minimal amount of colors required for a coloring that is free of conflicts is called chromatic number $\lambda_G$ and is depending on the structure of the graph $G$.

For the application of this model in Production Planning and Control the number of available colors is equal to the number of parallel, identical servers that are available. Every Vertex $i \in V$ is associated with an order, and every edge $(i,j) \in E$ is associated with a conflict between the corresponding orders, i.e. orders that are close in space or time and therefore can not be processed on the same server.

For this study, we look at regular ring-graphs with 24 vertices that are based on used small-world graphs (Watts & Strogatz, 1998). Such small-world graphs exhibit both high clustering as well as short average path length. Similar to Watts and Strogatz we study graphs in which every vertex $v$ is adjacent to “index neighbours” $v-2,v-1,v+1$ and $v+2 \pmod{|V|}$, thus making them actual neighbours. (Compare figure 1).

An overview of all parameters of the model can be found in table 1.

![Figure 1: Exemplary Ring-Graph (from Set1)](image)

The circular structure of these graphs is chosen to avoid artifacts otherwise to be expected at the boundary of the grid. Contrary to original small-world graphs the edges are not randomly rewired, instead additional edges are inserted in order to model further dependencies. This approach can be formalized as the following procedure.

1. Create regular Ring-Graph with $N$ vertices
2. Add edges between every vertex and his two upper and lower “index neighbours”
3. For every pair of edges that are not adjacent and for which the degrees of both vertices are lower than $mL$, add an edge with probability $p$
In order to compare the two heuristics, five sets of graphs were generated with the following parameters, presented in table 2. Each set consists of ten graphs generated with aforementioned procedure, and each graph has the chromatic number six.

**Table 2: Parameterization of evaluated graphs**

</tbody>
</table>

In order to find a suitable, conflict-free coloring for the studied graphs, a MAS is applied, as commonly used for the modeling of distributed control. With this approach an agent is deployed for a vertex of the graph G. In order to answer the research question, we compare two different agent heuristics, with the first one only having access to information about its direct neighbours, thus being purely decentralized. The second heuristic however can access additional information via a central information broker that keeps track of the global colour usage.

![Exemplary Graphs from Sets 2-5](image-url)
Both heuristics are visualized by means of flowcharts in figure 3 and 4. For the first heuristic, every agent acquires the coloring of every adjacent vertex and then chooses from the set of colours with the least amount of conflicts, thus relying purely on the locally available information.

Heuristic two starts similar by also acquiring the coloring of all adjacent vertices. In the next step however, it accesses global information about cumulative use of every colour. By intersecting the set of colours with least local conflicts with the set of colours globally least used, the resulting set contains only colours that fulfill local requirements and appear to be a sensible choice in order to reach a globally conflict-free colouring of the graph. If the intersection is non-empty heuristic two chooses the colour from this set, otherwise it falls back to choosing a colour from the set of least local conflicts.

With this setup in mind, both heuristics were applied to all five sets of graphs with a maximum number of 250 iterations each. Within these iterations, the agents for each vertex can sequentially apply the heuristic and thus determine their colour.
Since each graph has the chromatic number six, there is a conflict-free colouring with six colours. This approach however does not come without drawbacks, as only a limited number of graphs were evaluated. Thus, only a small number of possible graph structures is evaluated.

Findings
With both heuristics applied for 250 iterations to each set of graphs, the following results emerge. For 35 graphs a conflict-free colouring was found by at least one of the heuristic and for 19 graphs it was found by both heuristics. Table 3 gives a detailed overview of all results. For the remaining 15 graphs, neither of the heuristics was able to find a conflict-free colouring within 250 iterations. In the 19 cases in which both heuristics found a conflict-free colouring, the hybrid heuristic needed more iterations in only five of these cases. With these results, it becomes apparent, that neither of these two heuristics is even close to strictly dominate the other.

It appears that the performance of the heuristics is very dependent on the structure of the graph. As the vertices in all sets always have at least four edges due to the underlying ring structure, we focus on the inner edges that were randomly chosen in the aforementioned manner based on the parameters p and mL. To quantify these edges the average degree of the vertices in each set of graphs has been determined an is listed in table 3. Table 3 further shows the results for each set in particular.

</table>

Out of the 15 graphs for which neither heuristic was able to find a conflict-free colouring within 250 iterations, 14 belong to either Set3 or Set5. Both these sets feature the highest average vertex degree with 11.08 and 12.78 respectively.

In order to better understand the behavior of the heuristic, we review the results for a graph from Set3 in detail. In figure 5 said graph is displayed, while figure 6 shows the performance of both the purely decentralized (in blue) and the hybrid (in red) heuristic, which utilizes a broker of global information. The performance of both heuristics is measured as the mean of remaining conflicts for each vertex, hence if the mean is zero, a conflict-free coloring has been achieved (every vertex has zero conflicts with its neighbours).
Within the first 48 iterations, each of the 24 agents (one for each vertex) can determine its colour twice, and most of the conflicts in colouring are already resolved for both heuristic. The purely decentralized heuristic has conflicts between six pairs of adjacent vertices to resolve, while the hybrid heuristic has conflicts between two pairs of adjacent vertices to resolve. The resulting colourings for this exemplary graph is visualized in figures 8 and 7, respectively.

However, one characteristic striking our attention is that for both heuristics, the mean of conflicts per vertex is falling monotonously. Hence it becomes apparent that for this graph, both heuristics fall into a local minimum – and since every agent is always minimizing the conflicts for one vertex, the heuristics are unable to leave said local

---

**Figure 5:** Graph from Set3, Chromatic Number 6, p 0.4, mL 15, Average Degree 11.5

**Figure 6:** Performance for Graph X, comparison between purely decentralized (blue) and hybrid (red) heuristic

**Figure 7:** Initial colouring and colouring after 48 iterations of the purely decentralized heuristic

**Figure 8:** Initial colouring and colouring after 48 iterations of the hybrid heuristic
minimum. Consequently, both heuristics are unable to find a global minimum, which has no remaining conflicts in the vertex colouring. This yields insights for the design of Industry 4.0 applications as to the design of such systems. In order to reap the possible benefits of distributed control (such as better logistic performance, more reliable and agile planning), the coordination between agents and their behavior is critical. This becomes apparent for those graphs, in which a conflict-free colouring was not achieved due to a deadlock, stemming from the selfish behavior of agents. This coincides with Thomas et al. (2012), who list the prevention of deadlocks as a requirement for the successful cooperation between agents. With the increase of available information and increasing deployment of CPS in light of Industry 4.0, decision problems grow larger and larger – thus limiting the use and efficiency of central control approaches while increasing the attractiveness of distributed control at the same time. For future research, options range from the modification of the usage of global information, the expansion of available global information to the coordination between agents.

Conclusion
The application of both the purely decentralized heuristic as well as the hybrid heuristic, which additionally utilizes a broker of global information, allows for some interesting insights. While neither of these two heuristics strictly dominates the other, most of the graphs were solved by both heuristics. Due to the fact that there are graphs in which the purely decentralized heuristic is better as well as some in which the hybrid heuristic is better, this paper concludes that the performance of either heuristic is quite dependent on the structure of the graph, which is primarily describe by the mean vertex degree in these simulations. Moreover, the vast majority of graphs, which were not solved by both heuristics are those with the highest mean vertex degree, but trapped the heuristic in local minima that do not represent a conflict-free colouring. This can be explained by the selfish attitude of each agent that aims to reduce the conflicts of the vertex it represents. From a managerial perspective, this underlines one of the challenges of the coordination of distributed control: Deploying primitive agents for each logistic object that only act in the interest of the respective logistic object greatly increases the risk of being drawn into the sphere of a local minimum, thus missing the solution that yields the optimal logistic performance.

The aforementioned model and simulation setup however are not without drawbacks. For only a limited number of parameters graphs were created and evaluated, and both heuristics have been applied to only 50 graphs in total. For future research, a multitude of option presents itself. Firstly, the hybrid heuristic can be modified in the way in which it evaluates local and global information. Secondly, the global information delivered by the information broker could be modified or expanded, for example by the mean vertex degree. Lastly, and most apparently, both heuristics can be modified to allow for an increase in conflicts, in order to escape local minima.

Abstract

Decreasing food and drink waste in the home can have a significant positive environmental and economic impact. However, few empirical studies have been performed on this issue, largely due to the cost and resources involved. This study describes a modelling method that can incorporate complex household dynamics and allow challenging questions regarding household food waste levels to be answered. The results can help governments and businesses to prioritise the actions that will be the most effective and efficient in reducing the amount of food being waste in the home.

Keywords: Discrete Event Simulation, Household Food Waste, Food Waste Intervention

Introduction

Globally, food production accounts for 70% of water use, 90% of land use and 30% of greenhouse gas emissions. By only eliminating food waste, up to a third of these resources could be saved (Global Food Waste Not, Want Not, 2013). In high-income countries, the largest contribution to food waste is generated from households (Parfitt et al., 2010). As a result, decreasing food and drink waste in the home can have a significant positive environmental impact. Various factors can affect the amount of food wasted in households. These factors include but are not limited to how food is sold, how often it is purchased, its shelf life, how it is stored in the home, and activities relating to the preparation, serving and consumption of food (Quested et al. 2013).
Given this, the amount of food waste in the home can be influenced by businesses supplying food to the home (e.g. food retailers and food processors / manufacturers) as well as the decisions and action of people in the home.

Changes that could be made by businesses in the supply chain with the potential to decrease the food waste in households include increasing the shelf life and open shelf life of the food items, selling the items in smaller packages, introducing smart labels etc. (Schanes et al., 2018). The behaviours and practices that householders can adopt to decrease the amount of food being wasted are often grouped into planning, shopping, storing, preparing and consumption (Wunder et al., 2019). Specific actions include planning meals, making a shopping list, avoiding impulse purchases, storing certain fruit and vegetables in the fridge, preparing an appropriate amounts for meals, and storing and using leftovers (van Geffen et al., 2017).

However, the impacts of these changes and actions on household food waste levels are not certain. Ideally, pilot studies would be conducted and empirical data obtained to investigate the effects on household food waste levels. Though, few empirical studies have been performed, largely due to the cost and resources involved (Reynolds et al., 2019 and Stöckli, 2018). This makes it difficult for governments and businesses to prioritise the actions that will be the most effective and efficient in reducing the amount of food being waste in the home.

In order to overcome these challenges, a preliminary discrete event simulation (DES) model has been tested and is currently being developed further using empirical data as input. This household food waste simulation model (HHSM) can incorporate complex household dynamics and allow challenging questions regarding household food waste levels to be answered. It simulates the purchase, storage, consumption and waste of a specific food item (e.g. milk) within a household over time.

In the remainder of this paper, the structure of the HHSM is explained, followed by a sample of findings on how changes in package sizes, shelf life, open shelf life and date labels affects the waste levels for staple dairy items namely milk, hard cheese and yoghurt in UK households. Implications for policy makers and other decision makers relating to household food waste are also discussed.

**Methodology**

The amount of food items consumed in a household each day is not constant but varies from day to day (Evans, 2012). Moreover, many cases of food waste in households are associated with random events such as buying a product with a shorter shelf life than usual, changes in plans (e.g. a work-related commitment). These random events can lead to ingredients for a meal being bought but not prepared and consumed, and so are, often wasted at a later date (WRAP, 2007). Methods that only include an average level of consumption (e.g. system dynamics) that do not include variation over time would fail to incorporate an important dynamic within the system and, accordingly, the modelling results would be less realistic (Quested, 2013).

For this study, a DES model that embraces the complexity of household dynamics related to the purchasing, storage, consumption and wastage of staple food items has been developed. DES is a system-based approach that can incorporate stochasticity of a real-life system and models a system as a sequence of events over time (Delaney and Vaccari, 1989).

The interdependencies created in the modules (purchasing, storage, demand, consumption) of the model reflects many of the features that are important to household food and drink waste. Different variants of the model can be adjusted for different staple food items, household sizes and other household characteristics. Both quantitative and
qualitative research was used to inform the model. In addition, data from national surveys relating to food items such as purchasing levels and available shelf life has been used as input to the model. Verification and validation of the model is achieved through the investigations on milk waste.

**Household Simulation Model (HHSM) Set-Up**

The model consists of four modules. These modules are shopping, storage, demand and consumption. Each module can be customized for household size and the behaviour of various household archetypes decisions on shopping, storing and consuming numerous staple food items.

Note that HHSM models a single food product and single household in any given simulation. To model the effects of changes (e.g. to products) across a population, a range of household types are required – these have been developed to help model the impact in the United Kingdom (UK), the country of interest for this project. The user also needs to customize the model for specific products.

The model also focuses on food that is wasted because it has not been used in time: thrown away because it has gone past the date on its label, gone mouldy or become rotten. This may be because too much was purchased, pack sizes were too large for a household’s needs, date labels were misinterpreted, items were not stored correctly in the home, or the shelf life of the product was relatively short. The model does not include food that is wasted because too much was prepared or served, rejected (e.g. due to a fussy household member), accidentally dropped on the floor, or due to appliance failure. It only focuses on food waste in the home; it does not model food waste in the supply chain.

Next, the description of each HHSM module is given briefly.

**Shopping Module:** Households can purchase food items from main shops and top-up shops. Main shop visits occur mid-week on either a Tuesday, Wednesday or Thursday, as randomly determined at the beginning of the week as the most households in the UK do a main shop approximately weekly. The amount of food item purchased at a main shop is fixed for every visit since people tend to have set habits when they shop for staple foods. The size and number of packages that will be purchased from the main shop can be set by the user regarding the household archetype and food item. If the household checks the fridge before shopping, the amount bought is adjusted accordingly by the model. For instance, if a household buys 4 pints of milk regularly on a main shop, but if they already have 2 pints in their fridge, they only buy 2 pints at this main shop visit. The probability of checking the fridge before shopping is another variable that can be set by the user for the household archetype under observation. A top-up shop is triggered if the household runs out of or is about to run out of the food item. This trigger level can be defined by the user. If the amount of food item in the home falls below the trigger level, there is a chance that the top-up occurs on that day or on the following day, provided no main shop occurs. The size and number of packages that will be purchased from the top-up shop is also fixed and can be varied by the model user.

Once the packages purchased from the main shop and top-up shop are set, the shelf life and open shelf life of the item is assigned to each package. Available shelf life and open shelf life is set by the user for the product. Available shelf life is the difference between the date the product is purchased and its use-by date. The shelf life of a product is defined as a probabilistic distribution to represent the case in real life. Open shelf life is the advice on the packs that is usually stated as ‘once opened use within x days’. Open shelf life can be defined as a deterministic value by following the guidance on the packages. Moreover, these values can be altered for different household archetypes to
reflect the degree to which the household adheres to these date labels; previous research 
has shown that many households are prepared to eat food after the dates on the packaging 
(WRAP, 2011).

Storage Module: Food items can be stored either in the fridge or freezer. After the 
shopping, packages are put in fridge or pantry depending on the staple food item. It is not 
common to purchase the staple food items frozen. However, depending on the household 
behaviour, staple food items can be frozen after purchase. The user can define the 
likelihood that the household will freeze the items that are about to expire. In that case, 
both unopened and previously opened packages can be put in the freezer. Once a package 
is put in the freezer, the frozen shelf life and thawed shelf life is assigned to that package. 
Frozen shelf life is the guided storage time of the food item in the freezer. Thawed shelf 
life is the recommended timeframe that the item needs to be consumed within once it is 
defrosted.

At the beginning of each day the fridge and freezer are checked for items that are 
expired and about to expire. The expired items become waste and the total waste is 
reported. In the case that the household choose to freeze the items that are about to expire, 
these items are put in the freezer. The likelihood that the household choose to freeze the 
items can be defined by the user.

Demand Module: Demand for the food item under consideration is created in this module. 
In this context, demand is how much of the food item in question the household would 
like to consume. If the household has a sufficient amount of that food item, then the 
amount consumed will equal the demand. If there is insufficient, then consumption will 
be less than the demand, and the demand that was not fulfilled is recorded as an output of 
the model.

There are options to enter the daily consumption distributions for adults and children 
between ages 0-6 and 7-17. Once daily demand is generated, it is sent to consumption 
module.

Consumption Module: Once a demand signal is received from the demand module, the 
amount in the current open package is checked. If the amount in current open package is 
enough, the demand is satisfied and the amount in current open package is updated. In 
case that there isn’t enough in current open package, a signal is sent to storage module to 
open a new package. First, the fridge is checked for available packages. In case there are 
no packages in the fridge, the freezer is checked for available packages. Once a new 
package is opened, a signal is sent to consumption module that informs the new package 
is ready for consumption. The demand will not be satisfied if no packages are available 
both in fridge and freezer.

Input Parameters: The model requires a large range of input data to function. These 
include:

- Household size including number of adults and number of children between ages 
  0-6 and 7-17
- Probability of consuming the item daily for adults and children
- Daily consumption amount (as a probabilistic distribution) for adults and children
- Regularly purchased package size of the item, number of packages purchased at 
each main shop visit, number of packages purchased at each top-up shop visit
• Probability of shopping list making and adjusting the amount being bought accordingly
• Average shelf life of item (deterministic or random), open shelf life of item
• Trigger level for top-up shop, likelihood of visiting the top-up shop on the day that the top-up shop visit triggered (if not visited on the same, it is visited on the next day)
• If the product can be frozen: Turn on/off freezing, Frozen shelf and thawed shelf life of the item, Likelihood of freezing the item that is about to expire (either open or unopened package), Probability of consuming a frozen item

Output Parameters: The model records various information from each run of the model. Of primary interest are the headline indicators:
• Total amount purchased
• Total amount consumed
• Total requirement/demand
• Total requirement not fulfilled due to no product in fridge or freezer
• Total amount wasted and the details on cause of the waste: Total waste caused by available shelf life, Total waste caused by open shelf life, Total waste caused by frozen shelf life, Total waste caused by thawed shelf life

Each of these variables are recorded for the whole of the model run (usually set to 10 years).

Application of HHSM on UK population
The challenge is that the HHSM models a single household in any given simulation. However, it is useful to use the model to understand how an intervention affects the food waste generated from a range of households across a given population. Therefore, the changes relating to an intervention need to be modelled for several different household types. The use of household archetypes is being investigated as the most promising route to bridging the gap between individual simulations and creating inference for a whole population. In order to use the HHSM to obtain insight on waste levels for UK population, first, different household archetypes and their weights were defined so that the UK population is reflected by the archetypes. Based on WRAP’s consumer segmentation research, 7 household archetypes were created to provide a range of households encompassing different numbers of occupants, and a range of practices relating to food and food waste (WRAP, unpublished). Weighting factors were determined to ensure that the average number of occupants in the households reflects the UK average. Description of these archetypes and their weighting factors can be found in Table 1.

For the baseline models of each product, the simulation model was set up with the inputs determined based on characteristics of these archetypes such as the number of people in the household, shopping patterns, consumption patterns, the attitude to food safety and date labels, and the management of food in the household. These inputs were gathered from the subject matter experts and following sources:
1. WRAP’s retailer surveys (WRAP, 2012; WRAP, 2017), which is a survey across UK retailers of a range of factors believed to influence household food waste for a selection of products,
2. The National Diet & Nutrition Surveys (Gov.uk, 2019) which assesses the diet, nutrient intake and nutritional status of the general population of the UK,
3. Customer segmentation survey conducted by WRAP, which includes shopping and consumption patterns, the approach to food safety and date labels, freezing behaviour, and handling of food in the household.

Table 1 - Household Archetypes in UK population based on consumer segmentation research conducted by WRAP

<table>
<thead>
<tr>
<th>Household Archetype</th>
<th>Brief Description</th>
<th>Weighting factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aspirational Discoverers (AD), Family</td>
<td>4-person HH, younger children, willing to take more risks, confident, good planning, moderately likely to throw away leftovers, moderate portioners.</td>
<td>7.8%</td>
</tr>
<tr>
<td>Functional Fuellers (FF), Single</td>
<td>1-person household, less willing to take risks., low confidence in the kitchen, poor planning, likely to throw leftovers, moderate portioning.</td>
<td>14.3%</td>

<td>4-person household with (generally older) children, medium confidence in the kitchen, good planning, leftovers will be used, good portioning.</td>
<td>13.2%</td>
</tr>
</tbody>
</table>

Once the baseline models were set and validated for each product under investigation, the necessary scenarios were defined to understand first the magnitude of the effect of the input parameters and second the possible interventions to decrease food waste. These interventions include, but are not limited to, changes in package sizes, changes in food labelling terms (i.e. use by date vs. best before date), changes in freezing guidance, extensions on shelf life and open shelf life with new technological developments on smart date labels etc.

The next section summarizes a sample of possible findings that can be acquired by employing HHSM for the UK population.

Findings
The results of this tool can be explored to help inform public engagement on the issue of food waste in the home, and discussions with the food industry on changes to products, packaging and labeling that could help reduce food waste at home. This section provides a sample of findings from the HHSM for dairy products’ waste levels. The waste level is defined as the percent of purchases wasted due to not being consumed in time (i.e. during open shelf life that is guided on the package, before expiration date). The quantitative results presented in this section are strictly only applicable to households that act as those described. Real households will differ from this simplified behaviour. As a result, the quantitative results in this section should be seen as indicative rather than exact.
**Hard Cheese:** Hard cheese, such as cheddar and parmesan is one of the dairy products that are subject to substantial variation in how people store it once opened. Development of smart packaging for hard cheese products and giving the right storage guidance is highly valuable. As a result, the waste level caused by open shelf life for hard cheese is of high interest. The HHSM is employed to understand the effect of open shelf life on waste level for hard cheese across the various household types and whole population. For instance, open shelf life guidance for hard cheese in the UK is 7 days. Figure 1 summarizes the changes in the waste level as the open shelf life varies from 7 to 14 days. According to the modelling results, single-occupancy households have the highest waste level per person which is expected and in accordance with previous research. The results suggest that open shelf life impacts strongly on waste. Note that the magnitude of the effect of the open shelf life on waste level decreases as the open shelf life period increases. Innovations that increase the open shelf life of hard cheese by one week can decrease the waste level by approximately up to 15 percentage points, from 17% to 2.3%.

![Figure 1 - Waste level outputs of hard cheese across the household archetypes and whole population as the open shelf life varies from 7 to 14 days](image)

**Milk:** People’s use of dates is linked to their understanding of what is meant by those dates and also factors in their perceived needs according to particular products (WRAP, 2008). Currently, milk can be found carrying a “best-before” date in UK. HHSM is used to measure the change of waste level in milk hypothetically if all milk bottles displayed with best-before date label. The experiments took into consideration the understanding of the households what is meant by those dates. Across the population, changing from “use-by” to “best-before” date label, on average, leads to extending the consumption period in the home by one day which is calculated based on the findings of Thompson et al., 2018 and the discussions with subject matter experts. This leads to decreasing the waste level for each household archetypes as seen in Figure 2.

According to the results in Figure 2, switching the date label from “use-by” to “best-before” can decrease the percentage of milk purchases that are wasted from 4.4% to 1.8% for the population-- which is about 8 tonnes of milk yearly. Note that this is a hypothetical example and the safety of consuming milk one day beyond the use by date and extending open shelf life by one day needs to be confirmed with competent authorities.
The change in waste level of milk by switching the date label from “use-by” date to “best-before”

Yoghurt: Yoghurt is considered a staple food for several cultures. In the UK, it is one of the dairy items that is purchased regularly. In general, 6-7% of the yoghurt purchased by UK households is wasted because it is not used in time (i.e. before it is thrown away because it went mouldy / off or it deteriorated in quality) (Quested and Liam, 2014).

The size of packs available to consumers can influence whether or not they are left with surplus food. One of the main interests for yoghurt was to see the effect of purchasing smaller multi-packs versus single big pots on the different household archetypes and the whole population. The waste levels for these two extreme scenarios where household only buy multi-packs or big pots are summarized in Figure 3.

As it can be seen, one-person households have the highest waste percentage per person and four-person households have the lowest waste percentage per person for both scenarios. Buying yogurt in smaller multi-packs eliminates the waste caused by open shelf life since the small pots are usually consumed immediately once opened. For single
big pots, the main generation of waste is caused because the item is not consumed in time once the pack is opened. Overall, consuming only smaller multi-pack yogurt can decrease waste level by 25%, compared to only consuming single big pots.

To summarize, the household food waste model reflects the probabilistic nature of the dynamics of food related activities within a household. Consequently, it gives results on the effects of waste prevention actions that are sufficiently accurate to base many decisions. The magnitudes of the effects of waste prevention actions can be estimated by setting and employing this tool.

Conclusion
The generation of waste in the home requires an understanding of both the flow of food through the home and social factors (i.e. how people interact with the food). This work suggests that system-based approaches to considering waste prevention in the home can increase understanding of the issues and determine the approximate impact of potential interventions. This research delivers a quality assured method for rapidly testing many food waste reduction interventions and provides an evidence base with which policy makers, industry and governments can act upon. The modelling technique (DES) is not new, but its application to food waste in the home is novel and provides many useful insights. The developed model can incorporate a wide range of products and household dynamics critical to food waste. Moreover, this model can act as a tool for explaining how waste generation can be conceptualised. The results from this ongoing study will provide guidance on the most effective actions to reduce household food waste.

Acknowledgments
Research presented in this paper was co-funded by the Economic & Social Research Council Impact Accelerator (Project title: “Simulating Household Food Waste: A Research and Policy model”), and WRAP. We would like to thank Professor Lenny Koh and Dr. David Evans for their support and guidance.

Abstract

Oil refinery procures oil from supplier to meet the customer’s oil demand. Thus, one of the most important decisions that oil refinery has to make is to allocate amount of oil procurement in spot and forward markets to meet the all the demand. Under the uncertain demand, difference between realized oil demand and forward oil quantity can be procured in the spot market. By introducing procurement flexibility such as inventory and financial derivatives like bilateral contract in the forward market, oil refinery can obtain desired balance profitability and risk tolerance with CVaR.

Keywords: Optimal oil procurement, spot and forward markets, financial hedging, Conditional value at risk

Introductions

This study intends to model the optimal quantity for maximizing the profit and minimizing the risk of oil price volatility. In addition to traditional JIT procurement, spot and forward contracts have emerged for oil procurement. By entering the advance markets which are called forward and future markets, oil refineries can purchase their optimal quantity and meet the uncertain stochastic demand. Also, they can hedge their fluctuation of stochastic oil price. Due to the soaring volatile oil markets, oil procurement problems have received increasing attention. Jan and Stefan (2010) already proved the benefit of participation in advance procurement markets and derivative markets. The reason for entering advance markets is primarily for meet the uncertain demand. After meeting the demand of the oil, we can partly hedge the fluctuation of oil price in advance markets. To the oil refinery, the fluctuation of oil price is significant to their oil procurement activity. In the US oil industry, 85 percent cost of operating activity is oil procurement cost. In the end, oil refinery can reduce oil procurement cost by entering spot and forward market. By introducing procurement flexibility such as inventory and financial derivatives like bilateral contract, put option, and call option in the forward market under the uncertain demand.

We analyze oil procurement problem under uncertain future procurement oil prices and oil product demands. An optimization model is presented that finds best quantity of advance procurement of oil and spot-market procurement. Also, derivatives such as
bilateral contract and call option and put option in the forward market can hedge the volatility of oil prices.

The rest of this paper is organized as follows. In section 2, literature review is presented. In section 3, Base model and parameters are described. In section 4, the conditional value model is presented. In section 5, a Conditional value at risk is presented. Finally, the conclusions are discussed.

**Literature Review**

In the petroleum industry, crude oil procurement has been a critical issue for refineries, as it involves volatile demand and oil prices. The previous literature in crude oil procurement of the refinery can be divided into three streams: maximizing profit, minimizing financial risk in spot and forward markets, and integration of the two. While there have been many studies in finding an optimal quality of crude oil procurement to reduce costs and to maximize profits (e.g., Zimberg and Testuri, 2006) or to minimize financial risks through spot and/or forward market buying (Gaur et al. 2007; Secomandi and Kerke, 2012), recently a few studies have emerged in integrating these two important operational and financial aspects. Therefore, this study intends to develop a mathematical model for finding the optimal quantity of crude oil procurement in order to maximize an oil refinery’s profit and minimize the risk of oil price volatility. To do so, we extend the previous integrated single-period model (Ji et al., 2015) to a multi-period model by incorporating trade-off between profit maximization and financial hedging.

Fluctuating oil price needs to manage risk with Conditional value-at-risk. Oil refinery tolerate different levels depending upon their objectives and capital. The adequate representation and manage of risk are a critical test task for business success. A typical approach in risk management is to estimate and control VaR with a specified confidence level. Many papers already analyzed and considered CVaR as risk measure (Standislav, 2002; Xiaoping and Chen, 2002; James and Ahmed, 2008).

**Base model**

We develop the mathematical models that determine optimal order quantity to purchase both in spot and forward markets. Our mathematical models incorporate the major parameters of oil refineries where oil refineries can buy oil via forward contracts and spot markets.

We propose an integrated mathematical model of determining the optimal quantity and frequency of crude oil procurement in multiple periods in order to maximize an oil refinery’s profit and minimize the financial risk from demand and price uncertainty. The model incorporates the major parameters of oil refineries, such as procurement, transaction, transportation, inventory and production costs as well as demand price, which can buy crude oil in the spot market and/or through forward contracts. The model is nonlinear in nature, involving geometric Brownian motion (Secomandi and Kerke, 2012; Chen et al., 2015) and Martingales (Ji et al., 2015) functions.

- **Assumptions**
  According to risk averse economic agent, we can maximize profitability which is originated from bid-ask spread with equivalent probability measure. Under the absence
of arbitrage, transaction cost in spot and forward markets is equivalent to the existence of at least one probability measure. This bid-ask process follows the martingale condition.

- **Variables**
We denoted by $F(0)$ the time 0 nominal price of a forward contract with time $T$ delivery, and simplify it to $F$. This price evolves during the time $[0, T]$ as a known stochastic process $F(t) \in \mathbb{R}^+$, $t \in [0, T]$. However, we focus on the time $T$ forward nominal price, which is the spot nominal price $f$; that is, $F(t) \equiv f$.

Trading in spot and forward markets incurs transaction costs, that is, bid-ask spreads. Consistent with models studied in the finance literature (e.g., Constantinides et al., 2007), we model these costs as proportional. Let $A$ and $B \in (0,1)$. If the firm purchases spot one unit of oil at time $T$, it pays the spot ask price $(1+A)f$; if the firm sells spot unit of oil at this time, it receives the spot bid price $(1-A)f$. At time 0 the firm can forward purchase one unit of oil at the forward ask price $(1+B)F$. We do not allow the firm short sell oil forward. As this is suboptimal in the no arbitrage valuation framework that we use. However, a forward sale at time 0 of one unit of oil can be made at price $(1-B)F$.

Consistent with the theoretical work and the empirical evidence on the structure of transaction cost are larger than the forward transaction costs; that is, $A > B$.

The firm’s time 0 forecast for its time $T$ demand is $D(0)$, which we simplify to $D$. As the forward price, this forecast may evolve as a stochastic process, denoted by $D(t) \in \mathbb{R}^+$, $t \in [0, T]$, which is correlated with the forward nominal price stochastic process. However, we focus on the spot demand $d$ at time $T$; that is $D(T) \equiv d$. Since, the demand forecast and forward nominal process are correlated, so are the spot demand and nominal price.

For notational convenience, we define $E_t[.] = E[. | D(t), F(t)], \forall (t, D(t), F(t)) \in [0, T] \times \mathbb{R}^+$, expectation given $D(t)$ and $F(t)$ with respect to a probability distribution. Notice that $E_t[.]$ is not random variables at time $t$ because $D(t)$ and $F(t)$ are known at this time. That is, our notation does not distinguish between random variables and their realizations; which should be clear from the context. We simplify $E_0$ to $E$.

The firm needs to decide how much supply $q$ to procure forward at time 0. Such an optimal procurement decision can be obtained by solving the following optimization problem.

- **Objective function**

\[
V : \max_{q \geq 0} E[ (1 - A)f(q - d)^+ - (1 + A)f(q - d)^- - (1 + B)Fq]
\]

Where $(. )^+ := \max \{ . \ , 0 \}$ and $(. )^- := \min \{ . \ , 0 \}$. The first and second terms inside the expectation in optimization problem equation are the revenue collected from selling excess contracted supply on the spot market and cost of any supply shortfall. The third term is the forward procurement cost. The objective function in optimization problem equation and its optimal value $V$ are both expressed in time $T$ money, as money exchanged only at this time.

Due to the presence of the spot market, the firm always achieve 100% service level. Indeed, $q=0$ is a feasible solution to objective function. This solution corresponds to simply waiting until time $T$, observing the realized demand, and procuring this amount on the spot market. We denote the value of this spot procurement policy as $V^S := -E \{ (1 + A)f d \}$. We define the value of the forward procurement option, $V^P$, as the
additional value obtained by optimally procuring both in the forward and spot markets than only in the spot market.

\[ V^p = V - V^S \]

**Risk measure and Objective function**

For the risk measure, we conduct a CVaR, which is known as Mean Excess Loss or Mean Shortfall. According to Rockafellar and Uryasev, given a return distribution, the \( \alpha \)-CVaR is the conditional expectation of loss above the lowest amount for which the loss will not be exceeded with probability \( \alpha \); it is the expected loss in the worst \( \alpha \)% of the distribution. In this paper, because we consider CVaR associated with total cost, it is defined as the conditional expectation of expenses above the larger cost for which the expenses will not be exceeded with the probability of \( \alpha \). Figure 1 demonstrates the 95% CVaR of the total cost.

![Figure 1 –CVaR with total cost](image)

According to Pflug, CVaR is calculated as

\[
CVaR_\alpha = \inf_{q_\alpha \in \mathcal{R}} \left\{ q_\alpha + \frac{E_{\text{es}} \left[ \text{cost} - q_\alpha \right]^+}{1-\alpha} \right\}
\]

Where the optimal \( q_\alpha \) is the corresponding \( VaR_\alpha \) shown in the figure. Note that \( \alpha \) is the confident level and typically set to 95% while \( q_\alpha \) is the associated \( \alpha \) level value-at-risk. By minimizing the right-hand side of equation of CVaR, CVaR is as well as VaR can be obtained simultaneously.

As compared to VaR that lacks subadditivity and convexity as is ill-behaved, CVaR is a coherent risk measure with the following properties: translation invariance, subadditivity, positive homogeneity, and monotonicity. Hence, we use CVaR as the risk measure, and the objective function is to minimize the CVaR associated with total cost as

\[ \text{Min } CVaR_\alpha \]

Conditional value-at-risk was recently developed in previous papers. This method is quite general and can be used for any application involving optimization of quantiles. Also, development of this approach is mostly stimulated by finance applications.
Therefore, it will be explained in the framework of the financial contents. By optimization with conditional value-at-risk, our paper reduces risk which is consistent with fluctuating oil price.

**Results**
Each oil refinery tolerates different level of risk, depending on their objectives and capital. Fluctuating oil price can be a critical risk to oil refinery. Depending on oil price, their procurement cost which is 85% of the operating cost is affected significantly. In the end, a typical approach in risk management is to estimate and control VaR with specified confidence level such as 0.95, 0.99 or 0.999.

**Conclusions**
The results from solutions and sensitivity analyses are expected to provide important practical insights related to the optimal combination of spot and forward buying in multiple periods. The problem is highly relevant for the strategic decision making of crude oil procurement by oil refineries in the petroleum industry. Theoretically, the contribution may lie in developing a more comprehensive multi-period model of crude oil procurement by integrating both profit maximization and financial hedging issues. The results from solution and sensitivity analysis are expected to provide significant managerial insights to practicing managers.

Abstract

This study uses an international survey to explore experimentally what drives Industry 4.0 (I4.0) in manufacturing companies. For this exploration, we hypothesize that, ceteris paribus, companies that are insightful as to the contributions of I4.0 to their management objectives, are aggressive in their I4.0 implementation. These companies are expected to adopt innovator-type behaviors in practicing I4.0 and move forward more quickly in their I4.0 implementations. Companies with an organizational culture aimed at intensively focusing on practices to improve some value creation capabilities are confirmed to be the most aggressive implementers of Industry 4.0.

Keywords: Industry 4.0, Absolute supply chain orientation, Product development capability

Introduction

Industry 4.0 (hereafter, I4.0) is an initiative taken by the German government. It has been referred to as the Fourth Industrial Revolution, aimed at making manufacturing sectors globally competitive by way of digitization. This comprises emerging enabling technologies such as cyber-physical systems (CPS), the Internet of Things (IoT) and cloud computing (Kagermann et al., 2013). Although there is still no well-accepted definition of the concept (Lu, 2017; Xu et al., 2018), the aim of I4.0 has been clearly stated: “I4.0 is focused on creating smart products, procedures and processes” (Kagermann et al., 2013, p. 19). CPS-based management is expected to greatly improve industrial processes linked to manufacturing, engineering, material usage, and supply chain and life cycle management (Kagermann et al., 2013). Its impacts on companies and industries are perceived to be strategically significant and pervasive (Porter and Hippelmann, 2014, 2015). The implications of Industry 4.0 forecast by these reports and articles are promising and significant for companies.

I4.0 implementation generates benefits by renovating the value creation process under the umbrella of connectivity (Kagermann et al., 2013; Porter and Hippelmann, 2014, 2015). Emerging new technologies supporting I4.0, such as IoT and related technologies, cloud computing and CPS (Kagermann et al, 2013; Xu et al., 2018) enable the value creation process to be integrated vertically, horizontally and end-to-end to enhance the effectiveness and efficiency of the process (Kagermann, 2013). Westerman et al. (2014) define the challenge of renovating the value creation process through digitization in three phases: Creating a compelling customer experience (identifying new customer values), exploiting the power of core operations, and reinventing business models. Westerman et
al. (2014) also advocate the concept of transformation leadership as a driver of renovation. Transformation starts with the reenvisioning of the customer experience, operations, and business models and then moves on to the implementation stage per se. We are specifically concerned with the first two aspects here: reenvisioning, i.e., new value concepts and the operations to deliver them. Reenvisioning is a trigger of the renovation process by digitization. In this study, we focus on the capability to design a desirable configuration of new value creation processes that is commensurate with this reenvisioning. If this capability is weak, the thrust that drives renovation is also weak. We hypothesize that this capability determines the capability to carry out process renovation. This is the company’s capability to constantly seek desirable value creation processes and transform existing processes.

Based on a survey of IoT researchers, Haddud et al. (2017) ranked the benefits and challenges related to IoT usage for individual organizations as well as entire supply chains. However, given general technological progress such as emerging information technologies, the extent to which these benefits are actually realized differs from company to company. For example, the benefit level from better control and management of inventories, which is one of the most highly perceived benefits (Haddud et al., 2017), clearly depends on achievable lead time and the company’s demand variability levels. As for the challenges, the second-ranked difficulty, a lack of a clear understanding of IoT benefits (Haddud et al., 2017), which is a fundamental barrier to IoT adoption, is largely dependent on the company’s ability to understand which factors are currently disrupting existing supply processes and how these factors can be improved.

In this study, we focus on the enablers of I4.0 implementation. If companies understand what needs to be improved in the value creation process and how this can be done, they are motivated to implement appropriate Industry 4.0 practices due to the contributions that they make to any improvements, and are open to more aggressive implementations than would otherwise be the case. We explore what the drivers of I4.0 implementation might be. The following section is a literature review of possible drivers of I4.0 implementation. Then, in the third section, we develop our research framework and research hypothesis. The fourth section presents the results of the statistical analyses and the research implications, and the final section offers some conclusions.

**Literature review**

One enabler of I4.0 is clearly the emergence of new digital technologies that are triggering I4.0, including IoT (Kagermann et al., 2013; Yu et al., 2016; Lu, 2017; Zhong et al., 2017; Ardolino et al., 2018; Buer et al., 2018; Dalenogare et al., 2018; Xu et al., 2018). Apart from the papers cited above, a large number of engineering approaches that present applications of the new technologies can be found in this research category. This is possibility theory. In reality, final adoption and implementation of the technologies probably depend on the perceived benefits, perceived costs, and external pressures (Tu, 2018; Tu et al., 2018; Tu et al., 2018). Another enabler is management culture and, especially, the culture behind innovative activities drives I4.0 implementation (Yu et al., 2016; Mohelska and Sokolova, 2018). Digital transformation leadership advocated by Westerman et al. (2015) is considered to be part of this enabler. A conservative management culture can indeed be a barrier to the push to I4.0 (Westerman et al., 2014; Yu et al., 2016; Mohelska and Sokolova, 2018). Together these two drivers imply that the existence of promising technologies and innovative leadership can be a driver of I4.0’s renovation of the value creation process. This is persuasive but not clear in operational terms. We inquire into enabling factors that render innovative leadership reliable and confident of success through the preparation of operating conditions designed to avoid
risks. In this study, we are concerned with more tangible and normative managerial drivers than the innovative culture that drives companies to take advantage of new technologies to renovate their value creation process.

One such enabler of I4.0 that has been stated in the research is the lean orientation prevailing in the organization (Rüttiman, and Stöckli, 2016; Mrugalska and Wyrwicka, 2017; Tortorella and Fettermann, 2018; Buer et al., 2018; Yin et al., 2018). Tortorella and Fettermann (2018) proved empirically that lean orientation is positively related to I4.0 implementation in Brazilian companies. A lean orientation constantly focuses on supply process efficiency as an organizational culture. I4.0 focuses on the value creation process with the supply process regarded as an important part of this and seeks continuous resource productivity and efficiency gains under changing competitive and ecological environments (Kagermann et al., 2013). With respect to the relationship between I4.0 and lean principles, Rüttiman, and Stöckli (2016) clearly state that the lean production capability or knowledge is a prerequisite of I4.0 and that I4.0 has the potential to make lean production work better. The present research also focuses on this enabler. It also explores the enabler on the other side of value creation processes, i.e., the process of identifying customers’ new values (Westerman et al., 2014; Porter and Hippelmann, 2014 and 2015). Lean orientation is more closely related to supply processes. Value creation processes comprise these two processes. I4.0 aims to renovate the value creation processes (Kagermann et al., 2013; Westerman et al., 2014).

This study hypothesizes that the intensity of organizational orientation toward strengthening the value creation process, including its lean orientation, drives I4.0 implementation. This study is based on previous research (Morita et al., 2018) that showed that the product development and supply chain process capabilities lead to long-run high-performance manufacturing in an integrated way. This study proposes and proves empirically that these capabilities, including lean orientation, can be drivers of the implementation of I4.0 practices. Companies characterized by high capabilities of these two processes are expected to better understand organizationally how I4.0 practices can be related to strengthening these capabilities for future competitive situations than would otherwise be the case.

Analysis framework and hypothesis formulation
When considering value creation processes, we assume two generic processes to work. They are new value creation (value concept creation and its packaging for the market) and value delivery processes (Westerman et al., 2014). Below we recap the equation based on Little’s Law (Hopp and Spearman, 1996; Little, 2011) that comprises these two processes (Morita et al., 2015; Morita et al., 2018). Based on this equation, Morita et al. (2018) deduced two capabilities: Product development and supply chain management. The supply chain capability reflects the strength of a culture or strategic focus constantly executing four initiatives: lead-time reduction, just-in-time (pull) control, demand variability reduction, and enhanced quality conformance. It has been given the name absolute supply chain-oriented strategy (ASCOS) (Morita et al., 2015; Morita et al., 2018). Morita et al. (2018) defined the product development capability (hereafter, PDC) as the capability of integrating the wisdom of customers, suppliers and the company’s relevant functions into product development. Strengthening PDC implies companies are constantly improving knowledge integration among these key players to introduce new values into products and services.

\[
V_s^* = D (T_T + R_T) + B_s
\]  
Where:

\[
V_s^* = D (T_T + R_T) + B_s
\] (1)
Vs* = The volume to be secured in an entire supply chain
TT = The time to fully transform a unit of product in the chain with no waiting time (Hopp and Spearman, 1996)
RT = The interval time between inventory reviews for replenishment measured in the same time unit as TT
D = The estimated average demand rate per time unit defined in the same time unit as TT for the future period of (TT +RT)
Bs = The buffer stock level, to be determined depending on TT +RT with an allowable stock-out level

This equation can be interpreted as showing Vs* as a theoretically ideal level of inventory in the entire supply chain, given TT, RT, an assumed average demand rate and an allowable stock-out level such as 1%. This equation is defined as a whole controllable supply chain process extending to upstream and downstream partners. Any surplus over Vs* is waste and any shortage under V*, opportunity losses. Vs* should be minimal given D. So, shorter TT and RT, lower demand variability, fewer quality defects, and an appropriate replenishment mechanism are desirable in order to maintain the level of Vs*. It can, therefore, be said that there are four focuses that underlie the supply chain management capabilities (ASCOS): shorter lead-time focus, demand stability focus, quality conformance focus, and just-in-time focus (JIT or pull-control focus).

High ASCOS can increase value added by increasing D and price as well as reducing waste by improving throughput time, quality conformance, speed and reliability of delivery, and stable operations. On the other hand, PDC also contributes to the growth of D by introducing new values to products and services in addition to improvements to existing products and services. Also, high ASCOS and PDC capabilities may multiply the above effects by their interactive fit, such as refining product strengths and designs, including modular architecture for manufacturability (Morita et al., 2018). Enhancement of both of these capabilities results in improvements to the four above-mentioned ASCOS focuses in the value creation processes and leads companies to high-value creation. So, companies that always make efforts to improve these two capabilities in order to build more effective value creation processes (condensed in the above equation) are expected to relate the potentialities of I4.0 concepts and technologies to the improvements to the ASCOS focuses more easily than would otherwise be the case, as they understand what the existing barriers to renovating or improving the value creation processes are and what needs to be solved. Also, the aims of I4.0 overlap with their intentions in the sense of streamlining and renovating the value creation process, which is prone to disruption and inefficiency due to many factors, including increasing market requirements for customization, chronic fluctuation of demand due to saturated markets, unreliable and untimely data, slow and inappropriate decision making, and unpredictable machine malfunctions caused by smart digitization, and are exemplified by I4.0 concepts such as smart factory, smart product and CPS (Kagermann et al, 2013; Haddud et al., 2107).

High performer companies, characterized by high ASCOS and PDC, continue to make efforts to renovate or improve their value creation processes to adapt to competitive requirements by focusing on demand rate and variability, lead time, quality conformance and replenishment synchronized with demand (Morita et al., 2018). In this paper, this will be called the high performer approach (hereafter, HP approach). On the other hand, the approach under the I4.0 concept (hereafter, I4.0 approach) aims to strengthen the value creation process by focusing on creating smart products, procedures, and processes by taking advantage of digitization (Kagermann et al, 2013). A common aim of these two approaches is to seek optimal competitive value creation processes. The HP approach
focuses on the physical process factors of the value creation process and the I4.0 approach on digitization exemplified by concepts such as “smart factory”, “smart product”, and CPS. The configuration of the value creation process under the I4.0 concept as a whole is still in flux although its aims and potentialities through optimization by “smart” and “connectivity” have been theoretically stated (Kagermann et al., 2013; Porter and Hippelmann, 2014, 2015; Lu, Y., 2017; Buer et al., 2018; Xu et al., 2018).

This study proposes that the HP approach drives or supports the implementation of the I4.0 approach as a framework of navigating focuses for digitization. From the viewpoint of the HP approach, the lead time focus requires improvements in times for physical activities such as manufacturing and engineering, the physical movement of goods, set-up or changeover of machine tools, processing and transmission of data and information, decision making and judgments, breakdown and malfunction of facilities and machines, rework, procurement delivery and elimination of bottleneck phenomena. The quality conformance focus requires improvements in, e.g., the working conditions of people and machines, design for manufacturability, quality control systems and supplier relationships. The pull control focus demands improvements in activities such as a grasp on inventories, adaptation of the inventory level to be held or secured at each stage of the supply process, including manufacturing and replenishment order release to secure the inventory level (Monden, 1991). The demand variability focus requires increasing demand predictability and product strengths such as product dignity (Clark and Fujimoto, 1991), as well as the robustness of processes such as postponement (Walter and Bowersox, 1988), together with other focuses such as lead time reduction.

Companies that adopt the HP approach are considered to encounter many opportunities afforded by I4.0 driven by emerging digital technologies. Therefore, this research hypothesizes that:

Companies highly-driven by the HP approach, i.e., companies characterized by high ASCOS and PDC, are also more aggressive when it comes to adopting the I4.0 approach, and implement I4.0 practices more than would otherwise be the case.

Although there are a number of practices involved in the I4.0 approach, in this research smart factory and smart product will be used as proxies for the I4.0 approach to test the above hypothesis. These are two typical concepts used by Kagermann et al. (2013) to introduce the I4.0 concept and will be described in greater detail below.

Kagermann et al. (2013) wrote (p. 19): “Smart factories are capable of managing complexity, are less prone to disruption and are able to manufacture goods more efficiently. In the smart factory, human beings, machines and resources communicate with each other as naturally as in a social network” For their part, Burke et al. (2017) stated (p. 2): “A true smart factory can integrate data from system-wide physical, operational, and human assets to drive manufacturing, maintenance, inventory tracking, digitization of operations through the digital twin, and other types of activities across the entire manufacturing network. The result can be a more efficient and agile system, less production downtime, and a greater ability to predict and adjust to changes in the facility or broader network”. Porter and Hippelmann (2015) characterized the smart factory as networked machines which automate and optimize production bringing about efficiency and a reduction in malfunctions. Therefore, although there is still no single definition of smart factory (Strozzi, et al., 2017), taking into account the above-mentioned articles, the smart factory could be defined as having such characteristics as communicability between machines or facilities, self-controlled and autonomously optimized operation, and the
self-examining capability of working conditions. These are the commonly mentioned conditions that characterize smart factory (hereafter SF) operations.

Kagermann et al. (2013, p. 9) characterized smart products as those that are aware of the details of how they are manufactured and how they are intended to be used. Porter and Hippelmann (2014) defined smart products as those into which three types of components are embedded: Physical components, smart components and connectivity components. Physical components include mechanical and electrical parts. Smart components are operating systems such as sensors and microprocessors, which make the product function for its designed usage. Connectivity components give communicability to the product by wired or wireless connection. For their part, Mani and Chouk (2017) stated that smart products are distinguished by three functions: Sensor functions (to collect data about the environment), actuator functions (to actuate an action, controlled by some other entity) and network connectivity functions (including WiFi, Bluetooth or RFID). Therefore, in essence, from the above comments, it could be said that smart products (hereafter SP) have communication capabilities and are designed to optimally go through their life cycle stages from their manufacture to final usage thanks to their communication capabilities, with relevant external units such as machines and users such as customers.

Taking into account the characteristics of SF and SP, companies aggressively adopting the HP approach are expected to find the SF and SP concepts valuable for the construction of their value creation process, especially at all stages of the supply chain (Burke et al., 2017) and customer product usage processes. The latter is considered to contribute to the strength of product and demand predictability by enhancing the product’s benefits and high utilization (Porter and Hippelmann, 2014). Therefore, in line with our research hypothesis, when companies adopt a high-level HP approach they will closely follow an I4.0 approach and will achieve a high level of I4.0 implementation (represented here by SP and SF levels).

Measurement and analysis results
This study’s analyses are based on an international online joint survey on I4.0 involving 5 countries (Austria, Germany, Italy, Japan, and Spain) and three industries (Machinery, Electronics and Automotive) that compete globally with a high degree of competitiveness. An initial sample of 276 companies was obtained. However, it was decided for this research to use only data from companies with no missing values. This led to a final sample of 186 companies (Austria, 30; Germany, 36; Italy, 28; Japan 56, and Spain, 36. Machinery, 69; Electronics 59, and automotive, 55).

Questionnaire responses were measured on Likert Scales from 1 (lowest) to 5 (highest). This research assumes that such high levels of competition drive companies to strengthen their value creation processes with a heavy reliance on manufacturing and supply chain process I4.0 targets (Kagermann et al., 2013), and to take a more aggressive I4.0 stance than they would do otherwise.

The constructs used for this analysis are: a) the concepts representing the HP approach, which were explained above: ASCOS, PDC and Integrated Capability of ASCOS and PDC (as a second-order construct); and b) those that represent the I4.0 concept: SP and SF and Comprehensive I4.0 (second-order SP and SF construct). The responses in the questionnaires related to ASCOS and PDC are respondents’ perceived levels of the corresponding items compared to their strongest competitors. The responses to the questionnaires related to SP and SF are the perceived levels of implementation of their corresponding aspects.
The *Smart Product* construct was developed by five questionnaires. As stated above, a Smart Product is designed to optimally go through its life cycle stages from manufacturing to final usage by reason of its communication capabilities. The analyses for the development of this construct advised us to divide the above-mentioned characteristics into two stages: Work-in-process and finished product. Although the definition of *Smart Product* implies that products know how to be manufactured (Kagermann et al., 2013), nonetheless it was decided for this research to include the “smart” features of work-in-process parts in the Smart Factory construct (see below) as these parts’ smart features can be considered to be part of smart manufacturing operations (Zhong et al., 2017). Although this may be considered controversial and further analyses need to be conducted, for this study, “Smart Product” will only be defined by its finished product-related features.

So, the *Smart Factory* construct is measured by a) five questionnaires referring to production facilities, which reflect communicability, self-control, autonomous optimized operation and the self-examining capability of working conditions; and b) six questionnaires related to work-in-process parts with “smart” features that enable the production facilities to operate as expected in “smart” ways.

As shown below, the reliability and validity tests for these constructs, with data normalized by country, show very satisfactory values for the corresponding loading factors of their components, average variance extracted (AVE), composite reliability ($\rho_C$) and $\rho_T$-Cronbach’s alpha:

- a) **ASCOS**: Loading factors above .779; AVE=.694; $\rho_C=.919$; $\rho_T=.883$
- b) **PDC**: Loading factors above .915; AVE=.838; $\rho_C=.903$; $\rho_T=.905$
- c) **Integrated capability of ASCOS and PDC**: Loading factors above .862; AVE=.593; $\rho_C=.921$; $\rho_T=.83$
- d) **SP**: Loading factors above .771; AVE=.646; $\rho_C=.901$; $\rho_T=.864$
- e) **SF**: Loading factors above .710 (except one with .611); AVE=.550; $\rho_C=.930$; $\rho_T=.917$
- f) **Comprehensive I4.0 (smart factory and smart product)**: Loading factors above .765; AVE=.705; $\rho_C=.826$; $\rho_T=.601$

With respect to the discriminant validity of the constructs, the Heterotrait-Monotrait Ratio (HTMT) is 0.758 (somewhat lower than the 0.9 limit) between the second-order constructs (Integrated capability of ASCOS and PDC, comprehensive I4.0) and below 0.622 for the first-order construct comparisons.

*Figure 1* shows where the sampled companies are located on the ASCOS (X-axis) - PDC (Y-axis) graph. The two capabilities are positively correlated (.557). Four groups were defined using the ASCOS and PDC averages: High performer (HP)/Integrated focus (68 companies) (this means that both ASCOS and PDC are above the average); ASCOS focused (19), (ASCOS is above the average and PDC is equal to or below the average); PDC focused (44) (PDC is above the average and ASCOS is equal to or below the average) and Less focused (55) (both ASCOS and PDC are equal to or below the average).

Next, the mean difference between the HP group and the other three groups for the Comprehensive I4.0 construct are analyzed with ANOVA. *Table 1* summarizes the results: The columns show the mean values of the comprehensive I4.0 implementation variables for each of the plant groups (HP, ASCOS focused, PDC focused and Less focused). The High Performer/Integrated focus group values are seen to be significantly higher in all cases than the other groups’

Note: R² is the degree of freedom adjusted coefficient of determination. The figures in parentheses are t-values. Significant at p<0.000

All these results confirm the research hypothesis. Most significantly, the integrated capability of ASCOS and PDC present in HP group companies is more influential for I4.0 implementation than either ASCOS or PDC alone. If the focus of I4.0 is to be on the total value creation process as Kagermann et al (2013) stated, this result is understandable.

Discussion and conclusions
I4.0 is expected to provide a great number of opportunities for strengthening the value creation process. A distinction between I4.0 and traditional automation is that I4.0 focuses
on value creation process renovation through the “smart” concept characterized by connectivity involving all physical component units such as machines and products, company people, partners and customers. (Kagermann et al., 2013; Porter and Hippelmann, 2014, 2015). So, the capability most needed to take advantage of I4.0 concepts is the capability to understand how to enhance the effectiveness of value creation by aligning connectivity. This study shows that the two capabilities, ASCOS and PDC, can be drivers that effectively enhance connectivity to strengthen the value creation process. These capabilities may represent the competencies needed to understand which patterns of connectivity are essential from the viewpoint of the whole value creation process and to implement them quickly and steadily in interactive ways. As implications for materializing two key concepts of I4.0, Smart Product and Smart Factory, these are fruit that mature thanks to both ASCOS and PDC. In other words, and as a major managerial implication, companies should strengthen both their market and supply chain process focuses to develop Smart Product and Smart Factory—key components of I4.0—as they embody the driving forces of the whole value creation process, as shown in the equation (1).

In this study, many research points have not been addressed due to length restrictions. These include, for example: The adoption patterns of I4.0 technologies for Smart Factory and Smart Product, an explanation of the cross relationships between (ASCOS, PDC) and (SF, SP), an analysis of country and industry differences and the determinants of the contributions made by the effects of I4.0 implementation on performance, all of which are on our ongoing research agenda.

Acknowledgments
This study was supported by a grant from the Japanese Society for the Promotion of Science JSPS) from 2017-2019 (Project code number: 17K03952). This research has also been supported by projects funded by the Spanish Ministry of Education and Science (DPI2009-11148) and the Junta de Andalucía, Spain (Special action for HPM (Junta de Andalucía (ref. SBAPA 2015/006) and Project of Excellence SEJ-3841). We would like to express our sincere gratitude to the JSPS and to the Spanish institutions for their support.

Abstract

This paper analyses the theoretical and managerial contributions of action research (AR) studies in the field of Operations Management. First, it develops two corresponding frameworks to classify the different types of both research and managerial contributions produced by AR studies. Secondly, the paper then analyzes and classifies accordingly these different types of contributions from 54 AR studies found in Operations Management journals. Thirdly, the paper then proposes key avenues for improvement of the contributions of future AR studies, as well as ways to overcome the main challenges that such studies typically face.

Keywords: Action research, Research contributions, Managerial contributions

Introduction

The analysis of the contribution of operations management (OM) research to managerial practice has been a key concern for researchers for years. Already in the early 1980s, Buffa (1980) highlighted that OM was in the process of becoming a “functional field of management”. Craighead and Meredith (2008) stressed that while OM research had actually evolved towards a more direct observation of the phenomenon being studied, it was necessary to reinforce those efforts through such research methods as case and field-based studies, experiments and action research (AR).

The focus of our analysis in fact is AR, which according to Shani and Pasmore (1985, p. 439) may be defined as “an emergent inquiry process in which applied behavioural science knowledge is integrated with existing organisational knowledge and applied to solve real organisational problems. It is simultaneously concerned with bringing about
change in organisations, and developing self-help competencies in organisational members and adding to scientific knowledge. Finally, it is an evolving process that is undertaken in a spirit of collaboration and co-inquiry”. Therefore, its dual contribution in terms of both the academic and managerial dimensions as well as the collaboration between researchers and practitioners are two of the main features of AR.

In the OM field, in particular, Coughlan and Coghlan (2002) analysed the relevance of AR as a methodology that permits, at the same time, solving a problem for a firm and making a relevant contribution to theory as it represents the application of the scientific research method to practical problems and implies active collaboration between researchers and firms.

The aim of this paper is to analyse the research contribution of identified AR studies as well as the types of benefits that practitioners gain from these studies. Consequently, we want to answer the following research questions.

**RQ1: What kinds of research approaches are used in AR studies carried out in OM research?**

**RQ2: What kinds of practitioners’ benefits predominate in AR studies carried out in OM research?**

To answer these questions, we first review to what extent AR has been used in OM research. This allows building a database of articles using AR that can serve as the source to answer both RQ1 and RQ2. These results allow us to analyze the main challenges for AR to become more relevant in the OM field. Then, we develop a framework in order to analyse the contributions of these papers in both terms: research and managerial contributions.

Therefore, the goal of our study is to understand the dual contributions of AR studies in OM (to date), and to identify the main challenges for the use of AR in OM research going forward.

The structure of the paper is as follows: in section 2, it is described the dual purpose of AR and a framework is developed in order to answer the research questions. In section 3 we describe the methodology which resulted in a database of 54 AR studies in OM during the time period of 2000-2015. Section 4 presents our findings and in section 5 we discuss opportunities and challenges for the use of AR in the OM field.

**Theoretical background**

In this section we first describe the main requirements of AR in term of its dual purpose and collaborative aspects, and second, we introduce the typology used to classify the AR papers in terms of both research approach and practitioners’ benefits.

*Dual purpose in AR studies*

Several definitions of AR exist (e.g. Shani and Pasmore (1985) mentioned). To some extent these definitions reflect the evolution as well as the different approaches to AR. This can perhaps also explain why the meaning of AR, and the way it is applied, differs somewhat across disciplines. For this reason, AR is sometimes labelled as an “umbrella term” describing a variety of approaches and styles of research (MacIntosh and Wilson, 2003).

The implementation of AR in the OM field differs from the one found in other areas where AR originally emerged (medicine, psychology, sociology). In these fields the role of the practitioner is to be a “patient”, on which the researcher develops different experiments. In the case of OM, there is a relationship where both researchers and practitioners (firms), have the same hierarchical level and where there is a win-win relationship. The specific features of AR in OM studies, as compared to more traditional
AR studies, are important to emphasise as they highlight that the research objective should be of mutual interest to both the researcher and the practitioner.

A crucial aspect of a rigorous research design is a proper description of the unit of analysis. One aspect that differentiates AR based papers from case studies is that the unit of analysis is treated as an active object. The outcome is, therefore, both an action and research (Coughlan and Coghlan, 2002), where research is used to inform practice, and practice is used to inform research (Näslund, 2002).

AR projects are often characterised as cyclical in nature, corresponding to the cyclic loop of learning. AR projects go through a spiral of cycles (phases) of planning, action (implementing), observing (evaluating), and overall analysis and reflection as a basis for new planning and action (Ballantyne, 2004). In this spiral of cycles, each of these activities should be systematically and self-critically implemented and interrelated. The researcher is involved in the actual project, and then steps aside to meticulously reflect and analyse what happens in the organisation (Daudelin, 1996). Thorough understanding and analysis constitute a key requirement for taking new action.

The collaborative nature of AR is mentioned in the literature is another key aspect of AR and directly related to its dual purpose. In the research process, researchers and practitioners collaborate in all the AR cycles by sharing ideas and reflections the participation of the studied organisation in the cyclic research process will increase authenticity and trustworthiness of findings. Thus, research rigor is achieved in a collaborative manner. In this sense, Coughlan and Coghlan (2002, p. 233) write: "AR is a challenging approach to research because it requires confident and experienced researchers to cope with the uncertainty of the unfolding story and to be able to work as researchers exposed to the reality of organisational change in real time." Due to the requirements that derived from the collaboration between researchers and managers, a team-based approach is often recommended for AR studies.

As a corollary, figure 1 summarises the main features of AR in terms of assuring the dual contribution of those studies based on this methodology.

![Figure 1 - Main features of AR that assures the dual contribution.](image)

**AR in OM: theoretical framework**

For the analysis and classification of the dual contribution of AR studies in OM research (i.e., research contribution and practitioners’ benefit), we develop a theoretical framework that covers both dimensions.

**Analysis of research contribution**

We base the classification of research contributions on three distinct research approaches, which determine the path of conscious scientific reasoning: deductive/theory testing,
inductive/theory building and abductive/theory elaboration. Figure 2 illustrates the three research approaches as described in Ketokivi and Choi (2014).

**Figure 2 - Features of theory generation, testing, and elaboration approaches (Ketokivi and Choi, 2014).**

- **Deductive research/Theory testing:** This approach starts by reviewing existing theory. Then, logical conclusions are derived from this theory in the form of general laws presented as ex-ante hypotheses/propositions (H/Ps). Finally, these H/Ps are then tested empirically (Spens and Kovács, 2006) and general conclusions are presented based on the corroboration or falsification of the H/Ps. The driving force in conventional theory testing is deduction, i.e., explicit derivation of hypotheses from a priori selected underlying theory (Ketokivi and Choi, 2014).

- **Inductive research/Theory generation:** The knowledge of a general framework is not necessarily needed as a starting point. H/Ps are developed on the basis of empirical studies instead of previous observations (Spens and Kovács, 2006). In terms of theory generation, Ketokivi and Choi (2014, p. 234) state that “the premise is that in the context of the specific research question and empirical setting, explanation (theory) derives from exploration (analysis)”.

- **Abductive research/Theory elaboration:** It starts with the observation of a real-life phenomenon. The researchers initiate a creative, iterative process of “theory matching” and “systematic theory combinations” in an attempt to develop a possible theoretical framework or to extend the existing theory used prior to this specific observation (Spens and Kovács, 2006). Ketokivi and Choi (2014, p. 236) explain that “abductive reasoning involves modifying the logic of the general theory in order to reconcile it with contextual idiosyncrasies.”

*Practitioners’ benefit*

In order to classify practitioner benefits, we define three types/levels of contributions that the firms can get from an AR study: diagnosis, proposal and implementation.

AR studies contribute a *diagnosis* to practitioners when they describe and analyse a particular issue, but neither recommendation on how to improve the situation, nor specific proposals are then described in the paper. In this sense, the researchers primarily aim to identify (root) causes for the problems at hand.

Contribute a *proposal* implies that the researcher recommends some specific actions to the practitioner to be carried out in order to improve the situation. These recommendations can come in very different forms (e.g., a strategic plan or a change program). The recommendations, however, are not described as a specific manner and no actual implementation is reported in the paper.
We classify a contribution as *implementation* when the organisation dealt with in the AR study has already realised a proposed solution and the results achieved are reported as well. In AR studies classified in this category, researchers usually develop and describe a specific tool or model for the issues the practitioners face, and the benefits for the practitioners are quantified and there is an explanation of the implementation stages that have been carried out.

**Methodology**

**Selection of journals and articles**

We selected these journals as they are known to (1) publish empirical papers that use case study and other similar (AR kind of) methodologies (Barratt et al., 2001; Näslund, et al. 2010) and (2) they are cited for their scientific quality in studies that have analysed this for OM journals (Olson, 2005; Zsidisin et al., 2007).

The time period analysed goes from 2000 to 2015. Our initial search in the journals selected was for articles that included the word “action research” in the title, abstract or keywords. Then we removed from the initial database those papers that were purely theoretical or descriptive in nature and those that actually did not develop the AR methodology. In the end this resulted in a set of 54 papers for our analysis.

**Coding and analysis**

The analysis of the 54 AR studies identified was carried out as follows: first, each author analysed the same five articles to determine their theoretical and practical contributions. The results were then compared. Wherever there were disagreements in the classification, there was a joint discussion to refine the criteria for classification. As a result, we created a template with detailed criteria that permitted the authors to classify the papers in a distributed manner (one paper – one “reviewer”). When there were conflicts or doubts about the classification of an article, the rest of co-authors were consulted to find agreement about the best assignment for it.

**Findings and discussion**

**Descriptive analysis of action research studies**

Figure 3 shows the chronological evolution of the analysed papers. The low number of studies found illustrates the residual importance of AR in OM journals.
In terms of journals, IJOPM papers represent almost 40% of AR studies found, and IJPE, IJPDL and PPC cover another 30%. So, it seems that there are few OM journals that publish most of the AR papers, and therefore the degree of dissemination of AR in OM research appears to be very low according to our data set.

Analysis of research questions

RQ1: What kinds of research approaches are used in AR studies carried out in OM research?

We analysed the number of papers classified according to the three types of research approaches during the period of analysis (2000-2015). The distribution is not homogenous in terms of publications per years. In the category “theory generation or inductive approach”, 13 studies were published in the first 8 years and another 12 in the 5 years from 2010-15. Every single year in the period analysed at least one paper has been published, with the exception of 2009.

With regard to the 15 papers classified as “theory testing or deductive approach”, four of them were published in 2015, and six were published in the period 2010-2014. Although the majority of the AR studies in OM research have taken the “inductive or theory building approach”, our data set shows a slight trend to publish increasingly AR studies following the deductive approach. Finally, we found fewer papers corresponding to a “theory elaboration or abductive approach” and they appear to be spread randomly over the period analysed.

The analysis of our data set reveals a pattern similar to the one reported in Barratt et al. (2011), where they found as well as predominance of inductive papers (82%) over deductive ones (18%). As a research methodology, AR has proven to be valuable not only for inductive studies, but also for deductive or abductive ones. Appendix 2 provides a detailed description of the research contribution for each paper.

RQ2: What kinds of practitioners’ benefits predominate in AR studies carried out in OM research?

The number of studies classified according to the three types of practitioner’s contributions during the period of analysis (2000-2015) was also analysed.

In the period analysed, “implementation” is clearly the predominant approach in our data set. This dominance has even increased in the last few years. In this category, there is significant reporting in detail projects that have achieved very specific benefits for the companies collaborating. For example, Baker and Jayamaran (2012) reported a 27%
inventory reduction thanks to the AR project carried out. In some other cases, for example, Adebanjo et al. (2013), the description of the implementation is of more general nature, like the reorganisation of the supplier selection process, and no specific results are reported.

In the “proposal” category, the main contribution for practitioners in the three papers identified, consisted in recommendations about specific improvements to be carried out in the company. In Neely et al. (2000), for example, the recommendations were specified in the form of a workbook that provides guidelines for a process-based design of a performance measurement system. Shaw et al. (2001) developed a framework that aims to become a model of good practices for new product (or process) development (NPD) in the fine chemicals industry. Finally, Braz et al. (2011) focused on presenting a proposal to improve the performance measure system of the company at hand.

Many of the papers assigned to the category of “diagnosis” appear to follow a similar conceptual approach. Based on the analysis of one or more specific case-studies, the articles then developed a more general methodology. A representative example of this is Dey et al (2015). They developed a method for the strategic evaluation of suppliers based on seven case studies. Appendix 2 provides a detailed description of the practitioners’ benefits for each analysed paper.

How to advance one step further: opportunities and reflections
In order to identify the main challenges related to the dual contribution of AR within OM research, it is necessary to first analyse the combination of both research and practitioner contributions. This is presented in Table 2.

<table>
<thead>
<tr>
<th>Table 1 - Distribution of papers in terms of the dual analysis</th>

</tr>
</tbody>
</table>

The analysis of the different combinations reveals that the “inductive-implementation” is the most common one in our data set. This seems to be in line with van Aken et al. (2016, p. 2), where they explain that “most action research projects aim for case-specific improvements”. Though, we consider that the scope of AR should not be limited to an “implementation” approach, as we see a significant opportunity to leverage the main advantage of the AR methodology (i.e., its dual contribution), by pursuing more of the other possible combinations of dual contributions of AR studies (cf. left hand side of Figure 6).
The resolute use of multiple AR methodologies may allow researchers to carry out not only papers based on inductive approaches but produce also studies based on deductive and abductive ones. In this sense, Spens and Kovács (2006) highlighted that AR has specific features that favor the development of abductive studies. Specifically, one way to further develop AR contributions in OM research could consist on reinforcing the “breadth” of AR scope. So, AR should not be limited to implementation approach but to emphasise also the dual benefits offered by the categories of diagnosis and proposals. Moreover, doing so may allow developing AR studies based on abductive and deductive papers. This challenge is emphasised in Figure 6. Then, we identify and describe three main challenges that may help to reinforce the role of AR in OM.

**Developing the full potential of AR for practitioners**

The thorough review of the 54 papers with regard to their dual contribution revealed a very relevant finding: in general, authors do not report the managerial contributions with the same level of detail than the theoretical ones. It seems that due to the fact that journals are written for academics (and reviewed by academics), authors are only requested to work out the academic contributions. This is also the case when researchers use AR methodology, even if in this case managerial contributions are considered to be a distinctive feature of the research.

This has two main implications for our study. First, as already mentioned (cf. methodology section 3), we had to “remove” papers from our database where the authors reported the use of AR (in the title, abstract or keywords), but then we could actually not find any description at all of practitioners’ contributions in the paper. Secondly, sometimes we had to classify papers with regard to their managerial contribution based on a few single sentences, in which the authors summarised their contribution to practice, as there were no specific sections in the papers reporting this in a more detailed manner.

Given the characteristics of AR, a rigorous article should include a discussion of why AR was an appropriate form of research for the particular study. This is linked with the fact that AR studies do not have to be limited to “implementation” but may also be useful for the cases of “diagnosis” and “proposals”. Eden and Huxham (1996) stated that theory building in AR is incremental in nature. Similarly, Perry and Gummesson (2004) claimed that theory building in AR is conducted in small steps from the particular case to the general.
Consequently, the development of AR articles that highlight (and detail) the different contributions made to practitioners should be encouraged both in journals and conferences.

**AR projects versus AR studies**
In order to further enlarge the “breadth” of AR studies, we may rely on the concept of an AR project. McNiff (2016) emphasises in some way the concept of AR projects and the need of ensuring that action research projects are conducted with a high quality in both action and research and the need to be linked with a firm philosophical base.

As a consequence, we consider that the development of AR projects allows to move away from the traditional view of AR as “extended case studies”. This view of projects versus case study allows a higher intense collaboration between academic and practitioners and generates learning in the different stages of the AR.

In order to enhance AR projects, it is very helpful that they are implemented using a specific support infrastructure that allows the researcher to be involved in the practitioner’s organisation, which implies to establish a collaborative framework that permits the researcher to develop the project from inside the firm. Two examples of support infrastructure can be a research/business chair at a university sponsored by a company and a doctoral thesis. Regarding the first one, Avella and Alfaro (2014) explained how such a chair can be a useful tool for developing OM research projects based on AR methodology (e.g. Zuber-Skerritt and Fletcher (2007)).

**Action research as an open innovation practice**
A way to impel AR is to link it with open innovation and to show why it can be considered as an open innovation practice that combines the outside-in process with the inside-out process and co-operate with other companies in strategic networks. The analysis of AR studies in OM journals determines that dual contribution is a differential aspect of this methodology that has to serve to promote its use in both academic and business environment.

**Conclusions**
First, it has been found that AR studies in OM are usually based on inductive approaches that focus on problem solving. We consider that this view has to be overcome and we show that there are OM papers based on AR methodology that develop both deductive and abductive approaches and that, at the same time, the main contribution to the practitioner does not consist on giving a specific solution to a specific problem.

It is necessary to make both OM researchers and practitioners perceive AR as a tool that permits them a win-win relationship. To do so, it is recommendable to build an infrastructure that facilitate this kind of studies. More specifically, the development of specific tracks in academic and professional conferences devoted to enhance university-firm relationships or to encourage in PhD programs thesis based on AR would encourage researchers to carry out AR studies. The renaissance of AR as a methodology in the OM field will permit to reinforce the impact of academic research for firms, one of the most relevant challenges for any business research.

Abstract

This study aims to examine the inter-relationship between supply chain and quality management systems to find out possible integration or mutual support of these two systems towards sustainability performance, based on survey-based empirical methodology. Analysis results find positive mediating effects of quality management practices on the relationship between supply chain management practices and sustainability performance, while they illustrate insignificant mediating effects of supply chain management practices on the relationship between quality management practices and sustainability performance. Furthermore, a significant offsetting effect from simultaneous implementation of supply chain and quality management practices is suggested in the relationship with economic returns.

Keywords: supply chain management, quality management, sustainability performance

Introduction

“Sustainability management” by “adoption of best management principles, models and practices” is an approach to simultaneously achieve economic growth, social equity, and environmental performance (Kuei and Lu, 2013). Quality management (QM) and Supply chain management (SCM) are operations management initiatives that would be adopted for the sustainability management purposes. QM seeks to gain competitive advantages over a long period of time. QM practices contribute to elimination of wastes, defects, and poor-quality outputs to provide superior values to customers. However, QM is criticised for too much internal focus (Foster, 2008). Resource dependence theory suggests that a single organisation cannot be self-sufficient with their internal resources; instead, resource acquisition is necessary to create complementary resources (Flynn and Flynn, 2005). In the global market, lack of self-sufficiency forces organisations to shift from internal practices alone into the supply chain (Flynn and Flynn, 2005; Kaynak and Hartley, 2008). SCM, therefore, has attracted huge research interest. However, SCM is still somehow criticised for its narrow orientation with over-emphasis on cost and efficiency
The concept of supply chain quality management (SCQM) has attracted research interest since the 2000s. SCQM is suggested as a fruitful research field for the future (Foster, 2008). Several studies made efforts to conceptualise and provide better understand about SCQM such as Robinson and Malhotra (2005) and Foster (2008). Some studies compared principles of QM and SCM as well as identified common practices of QM and SCM and proposed them as SCQM practices (Fernandes et al., 2017; Foster, 2011). Some scholars empirically studied the contribution of SCQM on organisational performance (Zeng et al., 2013; Azar et al., 2009; Kaynak and Hartley, 2008). Various research methodologies are adopted including literature review and prescriptive suggestions (Foster, 2008), case studies (Robinson and Malhotra, 2005; Zu and Kaynak, 2012; Kuei et al., 2011), and survey-based empirical method (Zeng et al., 2013; Kaynak and Hartley, 2008). Although there are pioneer works in this field, more empirical evidence in the setting of emerging economies is needed.

This paper aims to test the underlying relationship between supply chain – quality management practices and sustainability performance in Vietnam-based enterprises. The study would not only enrich the literature of supply chain quality management and sustainability by offering new empirical evidence of the underlying relationship, but also provide managerial insights into how operations management practices should be utilized to achieve sustainability goals in a emerging economy. The remaining of this paper presents literature review to propose a research model and develop research hypotheses, followed by research methodology and results from data analysis. The last two sections provide discussions on important findings and final conclusions.

Literature review

Understanding about Supply chain – quality management

Quality management is used to one of prioritized approaches for manufacturing and service organisations to build-up their competitive advantages. Much of academic work has investigated the effectiveness of QM principles and practices. The impact of QM practices has proven significant on operational performance but not always on business performance (Sousa and Voss, 2002; Robinson and Malhotra, 2005). This would due to the fact that principles and practices of QM have been much internall focused (Foster, 2008; Zhang et al., 2011; Zeng, Phan and Matsui, 2013). Internal capabilities from excellent quality management of an organisation are no longer sufficient for the globally competitive market nowadays (Robinson and Malhotra, 2005; Vanichchinchai and Igel, 2011). An organisation could not exist alone and perform well without cooperation from its partners.

Suggested by Resource Dependence Theory, resource acquisition is increasingly important with any organisation in the globally competitive market (Flynn and Flynn, 2005). This process is strongly supported by the inter-organisational relationship (Oliver and Ebers, 1998; Flynn and Flynn, 2005). As such, the topic of inter-organisational relationship management or supply chain management has generated considerable interest. Moreover, with the globalization, organisations have no longer competed within the national boundary but in the global market (Vanichchinchai 2011; Flynn and Flynn, 2005; Kuei et al, 2001). In this context, SCM has been increasingly concerned as a weapon to respond correctly, rapidly, and profitably to market demand (Zeng et al., 2013; Kuei et al., 2011).

QM and SCM are originally different initiatives but have evolved to merge towards a common goal of customer satisfaction (Li et al., 2006; Zhang et al., 2011). Toyota
Production System or JIT production initiated in the 1960s emphasised the importance of perfect quality and supplier relationship. The integration of QM and SCM is suggested by many scholars as a critical factor to the success of organisations (Gustin, 2001; Narasimhan and Das, 2001; Hutchins, 2002; Pagell, 2004; Miller, 2002). From the middle of the 2000s, supply chain quality management has become a fruitful research direction (Flynn and Flynn, 2005; Robinson and Malhotra, 2005; Foster, 2008; Kaynak and Hartley, 2008). Several studies made efforts to provide better understandings about SCQM and proposed SCQM as an emergent research field for the future (Robinson and Malhotra, 2005; Foster, 2008).

Robinson and Malhotra (2005) defined “supply chain quality management is the formal coordination and integration of business processes involving all partner organisations in the supply channel to measure, analyse and continually improve products, services, and processes in order to create value and achieve satisfaction of intermediate and final customers in the marketplace”. Foster (2008) defined SCQM as “a systems-based approach to performance improvement that leverages opportunities created by upstream and downstream linkages with suppliers and customers”. In this study, supply chain – quality management is defined as a mutual supportive mechanism of quality improvement practices and supply chain management practices to ensure the quality of intra- and inter- organisational activities and smoothly manage resource flows between a focal firm and supply chain partners.

Research on supply chain – quality management

Although there is much attention on quality management and supply chain management in recent decades, the studies on these two fields tended to be separate (Vanichchincharoen and Igel, 2011; Fernandes et al., 2017). From the middle of the 2000s, supply chain quality management has been viewed from a more integrated perspective. Some studies identified common practices of QM and SCM in the literature:

- Fernandes et al. (2017) conducted a study on the integration of SCM and QM by identifying their common key practices from the literature. The five common practices of SCM and QM are leadership, management and strategic planning, stakeholders involvement and commitment, information, and continuous improvement and innovation. The study proposes a conceptual model to present key areas of SCM and QM and the relationship between them. The model suggests that integration and sustainability are important for both fields.

- Quang et al. (2016) proposed a conceptual framework to test the effect of SCQM practices on firm performance. The proposed structural model describes multi-level linkages among SCQM practices and between SCQM and performance. The study emphasises a research gap on the interactions among SCQM practices and the consideration of information and supply chain integration as SCQM practices.

- Mellat-Parast (2013) using a relational view of inter-organisational competitive advantage, developed a theoretical background for SCQM. The study reviewed the literature and proposed key practices of QM and SCM from a learning perspective. Quality practices at the firm level include top management support, information systems, employee involvement, process improvement, product/service design, and customer satisfaction. Quality practices at the supply chain level comprise trust, governance, information integration, process integration, and cooperative learning.

- Foster et al. (2011) aims to offer a better understanding of SCQM practices by comparing the management tools and methods of operations managers and supply chain managers. The results pointed out that more collaborative is management approach of supply chain managers whereas operations managers are likely to manage the supply
chain through procedural methods. The study found that on-the-job training, data analysis, supply chain management, customer relationship management, project management, and surveys are common practices adopted by both types of managers.

Some scholars empirically studied the impacts of SCQM on organisational performance:

- Zeng et al. (2013) empirically study the relationships among internal QM, upstream QM, downstream QM and their effect on quality conformance and customer satisfaction and loyalty. The results demonstrate dominant role of internal QM in the SCQM which imply a necessity to effectively implement QM internally before moving towards SCQM. Downstream QM mediates the impact of internal QM on customer satisfaction while upstream QM appears to be lack of influence on performance.

- Vanichchinchai and Igel (2011) studies the linkages among total quality management practices, SCM practices, and firm’s supply performance in Thailand’s automotive industry. The study develops and validates measurement instruments. Analysis results using structural equation modelling indicate that the impact of total quality management practices on firm’s supply performance is significantly positive not only directly but also indirectly through SCM practices.

- Han et al. (2007) examines the relationships among QM practices, supply chain integration, and firm performance in 229 Chinese organisations. By structural equation modelling, the results show that QM practices directly and positively impact on firm performance. Supply chain integration does not directly affect firm performance but indirectly affect it through QM practices.

- Lin et al. (2005) studies the relationship between SCQM and organisational performance in Taiwan and Hong Kong. Using structural equation modelling technique, analysis results show that QM practices are positively correlated with supplier participation and supplier selection. Supplier participation mediates the impact of QM practices on business results and customer satisfaction.

- Flynn and Flynn (2005), under the perspective of resource dependence theory (Pfeffer and Salancik, 1978), figured out feasible themes on the dependence between buyers and suppliers to create synergies. The study provides empirical evidence supporting for an integrated relationship between quality management and supply chain management.

As can be seen from the extensive literature review, the existing body of work on supply chain quality management could be classified into three categories. The first category is to understand an integrated concept of supply chain quality management (Foster, 2008; Robinson and Malhotra, 2005). The second one is to identify common practices of supply chain management and quality management and consider them as supply chain quality management practices (Fernandes et al., 2017; Foster et al., 2011; Quang et al., 2016). These studies mainly confined themselves at the conceptual level. The third category is to empirically study the relationship between supply chain quality management practices and organisational performance. These studies, however, mostly focus on evaluating QM issues in the context of internal and external supply chain (Quang et al., 2016). The constructs to measure supply chain quality management are extension of quality management constructs into supplier relationship and customer relationship (Kaynak, 2008; Zeng et al., 2013; Lin et al., 2005). There is a lack of consideration in critical supply chain management practices such as information management and/or process integration.

Moreover, performance measurements in the existing literature are primarily related to economic aspect (such as operational performance, quality performance, customer satisfaction, and so on). Little work has considered how supply chain – quality
management practices affect three dimensions of sustainability performance (economic, environmental, and social dimensions). To fill this research gap, this study seeks to answer a research question “How would the integration of QM practices and SCM practices affect sustainability performance?” by considering sets of critical QM practices and SCM practices and three dimensions of sustainability performance.

Analytical framework and hypothesis development
In the literature review, SCQM has been defined and studied from different perspectives. The first point of view considers SCQM as an extension of quality management into supplier management and customer management (Kaynak, 2008; Zeng et al., 2013). The second point of view regards SCQM as applying systems-based approach of quality management into the whole supply chain network (Foster, 2008). The third point of view demonstrates the synergy effect when SCM and QM systems are implemented simultaneously (Flynn and Flynn, 2005).

QM initiatives have been used to be a weapon to gain competitive advantages since the 1950s. The birth of SCM is considered as a response to the movement of competition from single firms to the supply chain. SCQM, from this point of view, refers to an extension of QM into upstream and downstream supply chain (Kaynak and Hartley, 2008) in which SCM practices would strongly support and complement for QM system to achieve performance goals of the organisation. Supporting for this argument, Vanichchinchai and Igel (2011) found significant indirect and positive impact of QM practices on performance through SCM practices. Moreover, Lin et al. (2005) also found that QM practices significantly impact on organisational performance through the mediation of supplier participation. The literature discussed above leads to following hypothesis:

*Hypothesis H1*: SCM practices positively mediate the relationship between QM practices and sustainability performance

From SCM standpoint, SCM is a broad management picture in which QM plays a critical role. The principle of QM, the system-based approach, would be applied into SCM to create an efficient SCQM system (Foster, 2008). High quality internal coordination and activities must strongly support for external partnerships in supply chain management (Lambert and Cooper 2000; Vanichchinchai and Igel 2011). As such, QM practices are

![Figure 1 – Research model](image-url)
expected to facilitate SCM practices (Vanichchinchai and Igel, 2011) towards performance objectives. Supporting for this argument, Han et al. (2007) found that supply chain integration does not directly affect firm performance but indirectly affect it through QM practices. Additionally, Zhu and Sarkis (2004) found empirical evidence that the higher QM adoption level facilitates the stronger impact of green SCM on performance. From the literature, hypothesis H2 is stated as followed:

**Hypothesis H2:** QM practices positively mediate the relationship between SCM practices and sustainability performance

The third perspective considers SCQM as an integrated result from simultaneous implementation of QM and SCM. Both QM and SCM pursue a final goal of customer satisfaction and loyalty, but they target different functional objectives of quality performance and delivery performance respectively (Vanichchinchai and Igel, 2009). Therefore, simultaneous implementation of QM and SCM would result in a synergy or a conflict (Vanichchinchai and Igel, 2011). Flynn and Flynn (2005) figured out the potential to pursue quality goal and supply chain goal at the same time to create cumulative capabilities and demonstrated this argument by providing empirical evidence. Kannan and Tan (2007) investigated the effect of operational QM practices in the supply chain context and found some significant synergy of internal and external practices. Hypothesis H3, therefore, is stated as followed:

**Hypothesis H3:** Simultaneous implementation of QM practices and SCM practices yields positive synergy effect on sustainability performance

**Research methodology**

The methodology adopted in this study is a survey-based empirical method. A questionnaire was designed to collect data from Vietnam-based enterprises. Quality management practices are measured by the following eight constructs: top management support for quality management, training, product/service design, quality data and reporting, process management, continuous improvement, problem solving, and rewards. Supply chain management practices are measured by the following six constructs: top management support for supply chain management, information sharing, information technology, process integration, strategic supplier relationship, and customer relationship. Sustainability performance is evaluated in terms of economic performance (economic returns, cost reduction, market performance), environmental performance (emission reduction, resource consumption reduction), and social performance (internal social performance, external social performance).

The questionnaire was sent to a list of 992 Vietnam-based enterprises, followed by reminder emails and phone calls to non-respondents during a five-month period from November 2016 to March 2017. Finally, a total of 144 valid responses was used in the analysis of this study. The response rate was 14.5 percent.

**Hypothesis testing and results**

In this study, mediating effect is tested using PROCESS macro with bootstrap method that is suggested by Hayes and Rockwook (2017). Before testing the hypotheses, reliability and validity of the measurement scales are confirmed by reliability tests including Cronbach’s alpha and confirmatory factor analysis.

**The mediating effect of SCM practices on the relationship between QM practices and sustainability performance (SP)**

To test hypothesis H1, total effect of QM on SP, direct effect of QM on SP when SCM holds a constant, and indirect effect of QM on SP through SCM are calculated. If direct
effect is insignificant while indirect effect is significant, then SCM can be deemed as a mediator of QM’s impact on SP, and vice-versa. The analysis results show that there is no significant mediating effect (indirect effect) of SCM practices on the relationship between QM practices and sustainability performance. Significant total impacts are mainly derived from direct impact of QM practices on SP. As such, hypothesis H1 is rejected.

Mediating effect of QM practices on the relationship between SCM practices and SP

To test hypothesis H2, total effect of SCM on SP, direct effect of SCM on SP when QM holds a constant, and indirect effect of SCM on SP through QM are calculated. If direct effect is insignificant while indirect effect is significant, then QM can be deemed as a mediator of SCM’s impact on SP, and vice-versa. The analysis results show that QM practices have complete and positive mediating effect (indirect effect) on the relationship between SCM practices and economic returns, market performance, internal social performance, and external social performance. Interestingly, QM practices show significantly indirect but negative effect on resource consumption reduction with coefficient of -0.50 (significant at the 5% level). In summary, the analysis results show some significantly positive mediating effect of QM practices on the relationship between SCM practices and economic return, market performance, internal and external social performance. As such, hypothesis H2 cannot be rejected.

Synergy effect from simultaneous implementation of QM practices and SCM practices

To test the synergy effect from simultaneous implementation of QM and SCM practices on sustainability performance, regression analysis was adopted where independent variables are QM practices, SCM practices, and QM practices multiplied by SCM practices (QM*SCM represents for synergy effect) and dependent variables are seven sub-scales of sustainability performance. From the analysis results, a significant offsetting effect was found in the relationship with economic returns (coefficient of -0.27,
significant at the 5% level). In the relationship with other dimensions of sustainability performance, simultaneous implementation of QM and SCM reveals insignificant either offsetting or synergy effect. It can be seen that no synergy effect is found by simultaneous implementation of QM practices and SCM practices. As such, hypothesis H3 is rejected.

**Discussions and implications**

Based on the results using aggregate constructs of QM practices and SCM practices, it can be seen that simultaneous implementation of QM and SCM would result in an offsetting effect on economic returns. That means if an organisation invests a huge amount in developing comprehensive QM system and SCM system at the same time, it may have a negative influence on their economic performance. This may be because QM and SCM systems target different primary goals. QM drives towards high quality performance while SCM prioritises responsive delivery performance (Vanichchinchai and Igel, 2009). It seems to be difficult for most of the Vietnamese enterprises to pursue both goals simultaneously because they have to cope with severe resource constraints. Therefore, one suggestion is that the organisation should consider to adopt either QM system or SCM system first, and followed by the other system later.

QM practices have directly significant effect on SP which constitute significant total effect of SCQM on SP even with or without mediating role of SCM practices. Meanwhile, SCM practices represent insignificant direct impact on SP but significant indirect impact on SP through QM practices. It can be seen that the impact of SCQM practices on sustainability performance is strongly facilitated by QM practices. The reason would be because Vietnamese firms have longer implementation experience of QM compared to SCM. QM has been adopted and improved to achieve a certain performance level in Vietnamese enterprises. SCM, on the other hand, was introduced and diffused into Vietnamese enterprises more recently. Therefore, it would be understandable for the fact that QM practices seem to strongly support and facilitate the influence of SCM practices on various aspects of organizational performance including economic, environmental, and social performance. This finding is consistent with an argument that SCM broadens the management scope into external relationships, but it could not work well without the support from internal collaboration and high-quality performance of personnel within the organisation (Lambert and Cooper, 2000). In this situation, quality management, despite being criticised for too internal focus, has become an essential foundation for supply chain management (Vanichchinchai and Igel, 2011). This argument is support by Flynn et al.
(2010), where they emphasised the prerequisite role of internal integration to external integration, which in turn affects business performance. This finding implies a suggestion on how enterprises should allocate their limited resources to achieve their primary goals effectively. From the above findings, firms in Vietnam should better well implement QM system before implement SCM system.

Conclusions
This study seeks to examine the underlying mechanism of SCQM towards three aspects of SP or the triple bottom line. The finding of a supportive relationship between QM and SCM is considered as a response to the calls from Foster (2008), Flynn and Flynn (2005), Robinson and Malhotra (2005), and Li et al. (2005) for further investigation of possible integration between two disciplines. QM practices appear to play a more fundamental and antecedent role compared to SCM practices towards sustainability goals. This result is consistent with Zeng et al. (2013) and Vanichchinchai and Igel (2011), which found that QM implementation within an organisation is considered as foundation for SCM implementation and as a prerequisite for effective SCQM implementation.

Although the study has some contribution to the literature and practices, it is important to note its limitations. Methodologically, the subjective nature of the study entails some bias inherent in survey based work. The study collects cross-sectional data by self-reported questionnaire which comprises question items regarding both practices and performance evaluating based on a five-point Likert scale. Although the authors tried to address the issue of this bias by asking for multiple respondents from each organisation, perceptual and individual bias may still exist. This limitation could be somehow handled in future research by adding more objective question items. Another limitation is from the data source, that is, enterprises in one country, Vietnam. This research could be extended to more emerging economies and also more developed economies for a comparative study.

Abstract
Supply chain disruptions (SCDs) remain one of the most significant threats to firms’ performance. In this study we investigate chief executive officer (CEO) stock options as an antecedent of SCDs. Based on an eleven-year sample of more than 2,000 disruptions in U.S. S&P 500 firms we conceptually and empirically explain an inverted U-shaped relationship between CEO stock options and SCDs. We contribute to research the investigation of a previously neglected antecedent of SCDs, a more nuanced view on the strategic impact of CEO stock options, and insights on the moderating effect of relative chief operating officer (COO) power.

Keywords: Supply chain disruptions, CEO stock options, COO power

Full Paper

Introduction
Business interruption risks remain a significant threat to firms’ performance. Despite the high importance of SCDs for academia and practice, their causes are neither conclusively identified nor empirically well understood. Moreover, even though their decisions directly influence the supply chain, the impact of decision makers in charge of operations management is also neglected in operations management research (Hendricks, Hora, & Singhal, 2014). In this context, stock options are supposed to evoke more aggressive risk-taking by otherwise rather risk-averse executives in alignment with the shareholders’ interests. The concept of stock options allows executives to participate from the potential upsides of high-risk decisions with limited downside risks due to their optionality. This also comprises an increased willingness to take risks with regards to supply chain
management. Recent studies are ambiguous regarding the effectiveness of CEO options and call for further research on contingency factors impacting managerial risk taking (Benischke et al., 2019; Wowak, at al., 2015).

By contrasting agency and behavioral agency theory, we investigate the impact of CEO options on SCDs and the moderating effects of relative COO power and market uncertainty (see figure 1). We draw upon a unique, hand-collected sample of more than 2,100 firm-year observations over the years 2006 to 2016 with more than 2,000 SCDs in 223 S&P 500 firms. To support our manual sampling process, we used a machine learning algorithm to identify potentially relevant SCDs from more than 450,000 press announcements.

Figure 1 – Simplified research model

Our study contributes to operations management research in multiple ways. First, we identify and empirically investigate CEO options as a widely neglected organizational antecedent of SCDs. Second, we establish an inverted U-shaped relation between CEO options and SCDs enhancing research on CEO options with a more nuanced perspective on the effects of CEO options. Third, our study highlights the importance of having a powerful COO in the top management team with regards to supply chain stability. Fourth, we emphasize the necessity of adopting a contingency perspective when assessing CEO options and SCD risks. Finally, we introduce machine learning as a supporting technique to empirical secondary data research in operations management.

Theoretical background

SCDs

Prevailing research on SCDs emphasizes their harmful consequences: Hendricks & Singhal in several studies found, that SCDs diminish stock returns, market and shareholder value, and reduce sales over several years following a disruption (1997, 2003, 2005). In line with Hendricks & Singhal (2003) we define SCDs as unexpected events in the supply chain or its environment that threaten the normal business operations of a firm. Existing studies on SCDs vary strongly in the events being considered. Based on related supply chain risk literature, we use a dichotomous classification to cluster the SCDs used in our study. First, we separate micro- and macro-SCD-risks being in- and external to the organization (Wu et al., 2006). As we in this study investigate the effects of CEO stock options on SCDs, we exclusively focus on micro-disruptions which can directly be influenced by the firms. Loosely following the meta-analysis by Ho et al. (2015), we consider the following micro-disruptions in our study: demand and supply mismatches, delays, outages (of machinery or production), strikes, product quality issues, recalls, infrastructural problems, and issues of adverse business conduct. In line with Hendricks
& Singhal’s understanding of supply chain management and its subsystems, we assume that executives either indirectly (through negligence of important operations processes) or directly (through active strategic decisions or conscious misconduct) effect SCDs (2014).

**Behavioral Agency Theory and CEO Options**

The basis of agency theory and research on CEO options is the separation of ownership and management in firms, leading to potentially diverging interests between shareholders (principals) and managers (agents) (Jensen & Meckling, 1976). Principals delegate the management of the business to the agent (i.e. the CEO), who is assumed to act in their best interest. In this context, agency theory assumes, that agents are risk-averse. Stock options are supposed to reduce the CEOs’ risk-aversion by offering the CEO the opportunity to profit from firm success while not suffering from potential loss (Wiseman & Gomez-Mejia, 1998). Since CEO options are meant to influence a CEO’s behavior, behavioral agency theorists pronounce the need to combine agency with behavioral decision theory to fully explain its effects (Martin et al., 2016). Behavioral agency theory enhances agency theory by prospect theory to explain managerial risk-taking (Wiseman & Gomez-Mejia, 1998). Prospect theory postulates that managerial decision behavior depends on individual valuation of potential gains and losses to the personal wealth (Kahneman & Tversky, 1979) with wealth being understood as current, just-received, and fully anticipated wealth. Accordingly, agents weigh anticipated future wealth against declines in current endowed wealth (Benischke et al., 2019).

**Development of hypotheses**

**CEO options and SCDs**

If not in charge of operations themselves, CEOs have a strong impact on strategic decision-making regarding initiatives that affect company operations, such as cost-reduction programs, process-oriented programs (e.g. quality management, working capital management), or budgeting (e.g. R&D spending) (Wowak et al., 2015). Overly risky decisions in pursuit of stock performance optimization, thus, have the potential to evoke SCDs. Whereas agency theorists postulate a linear relation between CEO options and managerial risk-taking, based on the behavioral agency theory we assume that the relation between stock options and risk-taking is more nuanced and driven by two latent interacting forces: the perceived benefits in case of success and the perceived costs in case of loss associated with higher risk-taking by the CEO. CEOs with a low stock option share have little incentive to take risky decisions, as they only limitedly benefit from increasing share prices if the high-risk initiative achieves anticipated results. However, they have much to lose in terms of non-financial wealth or imminent penalties. With an increasing but still moderate CEO option share, the financial incentive to take risks increases, as the fully anticipated wealth assigned to high-risk initiatives becomes more compelling. As risk-taking preferences of an agent vary depending on the executives’ framing of the situation and anticipated effects on the personal wealth (Sitkin & Weingart, 1995), the CEO will constantly weigh benefits and costs of risky decisions against his current endowed wealth. Up to a certain point depending on the personal risk-taking preference, the incremental benefits of taking additional risks will overweigh the perceived incremental costs and will cause CEOs to ignore indications of project failure, to be negligent about risk mitigation, or to ignore downside risks of their decision (Wowak et al., 2015). As a consequence, we assume SCDs to increase. Following our logic of decreasing marginal benefits and increasing marginal cost of taking high-risk
decisions, we argue that with a high option share relative to the CEOs total compensation, risk-taking decreases as the CEO considers a large part of his prospect wealth at risk.

**Hypothesis 1 (H1):** CEO options exhibit an inverted U-shaped relationship to the frequency of SCDs, such that firms with low and high CEO option shares will experience fewer SCDs than those with medium CEO option shares

**CEO options, market uncertainty, SCDs**

When analyzing managerial risk-taking behavior, market uncertainty being defined as the extent to which a CEO faces an unpredictable and unstable environment (Finkelstein & Boyd, 1998) is arguably of special interest. Uncertain markets are characterized by constant variations in customers, preferences, and competition and increased supply chain risks per se (Trkman & McCormack, 2009). This will enhance the perceived costs of additional risk-taking by the CEO. Moreover, research suggests that with increasing market uncertainty firms face higher complexity in their task environment and an increased need to review and adjust strategies continuously (Miller & Friesen, 1983). This increases the alignment efforts within the top management team (TMT), which restricts the CEO in making high-risk decisions. Finally, with less predictability of the market and a growing amount of personal wealth being linked to firm performance, CEOs tend to become increasingly risk-averse and seek to preserve personal wealth (Wiseman & Gomez-Mejia, 1998). As the marginal costs increase as compared to the marginal benefit related to additional risk-taking, the U-shaped relationship between CEO options and SCDs is flattened, thus SCDs decrease.

**Hypothesis 2 (H2): The inverted U-shaped relationship between CEO options and SCDs is (a) flatter in markets where uncertainty is high and (b) steeper in markets where uncertainty is low.**

**CEO options, relative COO power, SCDs**

Past research suggests that the increasing marginal cost curve counteracting the marginal benefits of CEO options might increase in the presence of a powerful COO. Power is defined as the extent to which the COO can influence the behavior of others and has the discretion to shape and implement strategic decisions in his interest (Finkelstein, 1992). The COO frequently is delegated responsibilities usually held by the CEO. He, thus, reduces power distance in the TMT and constrains the power otherwise centralized in the position of the CEO (Worrel et al., 1997). With increasing power of the COO, the CEO needs to more closely involve him when initiating strategic changes in a firm’s operations. By creating a task-oriented conflict between CEO and COO, decisions are made in a process of social interactions that reveals differing assumptions and expectations (Marcel, 2009). This alignment process will arguably constrain the CEO’s tendency to disproportionately focus on upside potential of high-risk decisions with regards to operations and, in turn, increase the CEOs perceived risk to be blamed with a negative outcome of a high-risk initiative if pursued against opposition. Second, power structures in TMTs can create conflicts among executives. By contending the power of the CEO, the COO takes a monitoring role towards the CEO. This is based on an inherent competition between the CEO and COO and the fact that a weak performance of the operations function being visible to the external labor market might harm future employment opportunities of the COO (Fama, 1980). Third, the functional backgrounds represented in the TMT influence the salience of certain organizational objectives and performance drivers (Marcel, 2009). While Hayward & Hambrick show that CEOs – a
role rather focused on output-oriented than internal processes – tend to be more risk-seeking with higher individual power (1997). COOs will presumably act in the foremost interest of their functional responsibility and, thus, will challenge overly risky decision based on a profound understanding of the operations function.

**Hypothesis 3 (H3): The inverted U-shaped relationship between CEO options and SCDs is (a) flatter, when the relative power of the COO is high and (b) steeper, when the relative power of the COO is low.**

**Data and methods**

**Sample**

to empirically test our hypotheses, we gathered more than 2,000 SCDs from PR Newswire press announcements in the Factiva database from 223 publicly traded S&P 500 firms in the U.S. between 2006-2016. Based on the taxonomy developed above, we identified key search terms to identify first relevant disruption announcements per category, following the procedure of Hendricks & Singhal (2005). To handle the number of announcements and support our manual coding process, we developed a supervised machine learning algorithm, using python 3.6 & scikit-learn libraries, to automatically identify potentially relevant announcements based on both, title and body of the announcements. We re-read all announcements tagged as potentially relevant by the algorithm to judge the appropriateness, discussed unambiguous announcements. We, then, clustered the announcement into the SCD categories introduced above, using triple coding technique and regularly testing for intercoder reliability (Daniel & Harland, 2018). We then merged this SCD sample with TMT data from S&P Capital IQ’s ExecuComp and firm characteristics from S&P Capital IQ’s Compustat.

**Measures**

We operationalized our dependent variable (DV) supply chain disruptions as count variable (i.e. the number of recalls of firm i in year t), ranging from 0 to 8 in our sample. Our independent variable (IV) CEO options was operationalized as the share of stock options granted relative to the total compensation of the CEO as reported by ExecuComp. Following prior research, we calculated this variable as a two-year weighted average (Wowak et al., 2015).

With regards to our moderating variables, we put our focus on the presence of the COO role rather than on the title as such, following Hambrick & Canella (2004). We operationalized COO relative power as the COO’s total compensation relative to the total compensation of the highest paid TMT member (the CEO). This definition implies that higher relative compensation ratios indicate higher power in the TMT (Daily & Johnson, 1997). We operationalized market uncertainty as the coefficient of variation of sales per industry on four-digit SIC code level in a given year (Tosi et al., 1973).

To increase robustness of our research model we included multiple control variables on firm-, industry- and TMT-level. On firm-level, we controlled for firm size, financial slack, operating performance, past financial performance using Tobin’sQ, R&D intensity, and capital intensity. On environmental-level, we controlled for market uncertainty, technological turbulence, and technological sophistication. On TMT-level we considered TMT size, TMT ownership structure, CEO duality, and COO relative power.

Since firms with a history of SCDs may be more likely to subsequently encounter problems, we included lagged DVs in all models. Finally, all research models contain year and industry dummies. We lagged all variables in our model (except for the DV) by
one year to account for the fact, that strategic decisions based on information in a given year, will take time to become effective (Souder & Bromiley, 2012). All continuous variables are winsorized at the 1.0% level to avoid bias from outliers.

**Model**

We use STATA’s generalized estimating equation (GEE) model to analyze our unbalanced and pooled cross-sectional time-series data, following structurally similar studies based on longitudinal data (Wowak et al., 2015). GEE measures the effect on the DV “population-averaged” across all units in the data set, thus, considering both, within- and between-unit variation. Unlike alternative approaches (e.g. random- or fixed-effect models), GEE can deal with potential heteroscedasticity and serial correlation as it accounts for both inter- and intra-firm variations (Shah et al., 2016). Moreover, GEE does not (wrongfully) omit “zero SCD” firms (Sine et al., 2003).

**Results**

Table 1 provides descriptive statistics (unstandardized) and correlations (standardized) for all variables used in our models. The top right part of the matrix shows Spearman’s rank-order correlations, the bottom left values show Pearson’s product-moment correlations. The fact there is no significant correlation between CEO options and SCDs might be a first indication that the relationship might indeed not be linear rather curvilinear / U-shaped.

**Table 1 – Descriptive Statistics and Correlations**

| Variables                          | M     | SD    | Min | Max | 1    | 2    | 3    | 4    | 5    | 6    | 7    | 8    | 9    | 10   | 11   | 12   | 13   | 14   | 15   | 16   |

Note: Table excludes Spearman’s rank-order correlations top right and Pearson’s product-moment correlations bottom left, p-values in parentheses; N = 2,131

As we have COO presence in only 53.6% of all firm-year observations we shrink our sample size by 990 observations with the inclusion of the COO power moderator and control variable. Accordingly, we tested hypotheses 1 and 2 ex ante in separate models without the COO power variables. We repeated the tests in a second group of models including the COO power moderator and variables to test hypothesis 3. This approach allowed us to test hypotheses 1 and 2 without a potential COO presence selection bias.
Hypothesis 1 theorized an inverted-U-shape relationship between CEO options and supply chain disruptions. Necessary condition for such a curvilinear relationship is a negative second-order effect of the IV in our regression model. In support of Hypothesis 1, model 1-2 shows that CEO options have a highly significant effect on supply chain disruptions and the second-order effect is significantly negative. In hypotheses 2 and 3 we theorized a flattening in the inverted-U-shape relationship between CEO options and supply chain disruptions by our interaction effects. A flattening (or steeping) of a quadratic relationship requires the regression coefficient between the interaction effect and the squared IV to be significant and positive (Haans et al., 2016). As depicted in our full model 2-5 the coefficients of both interaction terms are significant and negative, with their corresponding second-order effects being significantly positive. H1, H2, and H3, thus, are strongly supported.

Notes: Robust standard errors in parentheses. Included in the model were CEO options and supply chain disruptions. **p < 0.01, ***p < 0.001.
negative binominal distribution best fitting our count data DV. To ensure our results are not driven by model specifications, we reran the analysis with an ordinary least square (OLS) random effects model with robust standard errors (model 3-1) and with Driscoll-Kraay standard errors to rule out cross-sectional correlation (model 3-2) (Shah et al., 2016). Both models confirm the results presented above. Next, we reran our main model with two different specifications of our IV using an unweighted average in model 3-3 and annual values in model 3-4. Again, our estimations are confirmed.

Firms with COOs might be substantially different from firms without COOs. Unobserved factors (e.g. operations management experience of the CEO) might influence both, the decision to have a COO and supply chain related outcomes and bias the results of our study. To test for this potential sample selection bias, we applied a Heckman two-stage selection model (1979) in line with prior TMT research (Kim et al., 2016) and included an inverse Mills ratio (IMR) predicting COO presence in all our models 2-1 to 2-5. As the IMR is insignificant and all other results remain robust, our analysis does not suffer from a sample selection bias. The results including the IMR are shown for the full model in model 3-5. Moreover, we drew on multiple means to lower the risk of potential endogeneity in our study. Among other measures, we created an endogeneity control by regressing CEO options in \( t - 1 \) on eleven of its potential firm-, industry-, and TMT-level antecedents in \( t - 2 \) and including this predicted IV as endogeneity controls in our models 2-1 to 2-5. Again, the results remained robust in all models. We show the results for the full model in model 3-6. Given the results of the tests above, reverse causality and endogeneity do not appear to be a problem in our study.

Discussion

Theoretical Implications

Our findings have important implications for research on SCDs and the extensive literature on the impact of CEO options on executive behavior. First, we extend operations management research by investigating CEO options as an organizational antecedent of SCDs. We empirically show, that CEO options – especially at medium levels – increase the frequency of SCDs. Second, we contribute to strategic management research which investigates the effects of executive stock options. While research on this topic has long been dominated by two schools of thought – agency theory expecting more risky decisions and behavioral agency theory expecting less risky decision as consequences of stock options – our research conceptually and empirically adds a more nuanced assessment of CEO options to prevailing literature. Third, this study identifies both organizational and environmental factors that have significant impact on CEO option-induced risk-taking. Both, market uncertainty and relative COO power have a flattening effect on the relationship between CEO options and SCDs, thus, diminishing the CEOs willingness to take disproportionate risks with regards to operations management. As of today, research on performance effects of COOs is ambiguous (Hambrick & Cannella, 2004; Hendricks et al., 2014). Our findings underline the importance of a COO at equal terms with regards to supply chain stability and further confirms research underlining the importance of operations capabilities in the TMT as a source of competitive advantage.

Finally, our study advances strategic and operations management research from a methodological standpoint. As the algorithm is not limited to a predefined dictionary of relevant terms but constantly evolves based on the growing training data set, this approach might be an interesting alternative to dictionary-based approaches. Especially in times of “big data” that can hardly be managed manually anymore and for relatively new areas of research where no established dictionaries exist, this approach can become increasingly relevant.
Practical Implications
Our findings bring about two important implications for decision makers. First, we advise decision makers to carefully select and combine different tools of executive compensation. Whereas CEO options might not be the best incentive used by itself, they still might be a valuable tool to induce additional risk-taking if required. However, this decision needs to be made very deliberately, keeping in mind potential risks. We, thus, recommend decision makers to balance CEO options with other means of executive compensation such as stock that also have a downside potential and reward sustainable decision making. Second, if using CEO options, we advise decision makers to embed their usage in an organizational setting that either does not facilitate strategic individual actions by the CEO or, as this study has proven, has a relatively low power distance in its TMT to enable mutual control among executives.

Limitations and Avenues for Further Research
Our study is subject to certain limitations that provide interesting avenues for further research. First, while our study focuses on the effects of CEO options, future research should investigate the interplay of CEO options with other prevailing means of executive compensation (e.g. stock ownership) in predicting supply chain stability. Second, whereas we focused on CEO compensation, it might be of interest to investigate effects of additional TMT characteristics on supply chain stability. Third, research has a strong focus on the CEO when investigating the effects of stock options. Future studies could expand this scope to other TMT members’ roles and strategic outcomes in their areas of responsibility to better understand potentially diverging interests between different functional strategies.

Nontoxic communication strategies for pharmaceutical product recall operations: Empirical evidence of Chinese social media data

Baoyang Ding (b.ding@sussex.ac.uk)

University of Sussex, Business School

Abstract:
This study explored the public perceptions of pharmaceutical product recall operations based on over 100,000 Sina Weibo data of twenty-one drug recall events in China from 2011 to 2018. We found that: 1) the information agents of drug recall event are now mainly authoritative third-party media; 2) except for extremely serious product-harm crisis, public opinions of most events gradually degraded into non-toxic within two weeks, while pharma companies should take full advantages of the “transition time” to mitigate the explosion of negative public opinions; 3) the apology strategy is less effective and more proactive actions should be considered.

Keywords: Product recall, Public perceptions, Social media

Introduction
Till now pharmaceutical product recall events are prevalent due to mistakes in the pharma supply chain and the stringent regulations (Ball et al., 2018). In the connected world, a typical product-harm can spread fast through various social media platforms in the form of public opinions and sentiment of product recall (Spence et al., 2016). Companies recognizes social media as an irreplaceable platform to interactively communicate information to public during product recall advisory and for marketing (Lee et al., 2015). Especially for pharma products, due to the lack of technical knowledge, the public cannot fully understand the real consequences, and hence this may not similar to other products or mobile recall events (Chen et al., 2015). Hence, it is vital to understand how customers respond in the social media era context and to what
extent companies can leverage the information available in social media platform to
develop an effective product recall communication strategy (Wowak & Boone, 2015).
Even though social media is garnering importance its usage during crisis is embedded
with several challenges (Ki & Nekmat, 2014; Li & Li, 2014). Therefore, the main
purpose of this study is to answer: 1) who are the “information leaders” of Chinese
pharmaceutical product recall events; 2) how publics respond to different clusters of
recall events in China.
This article is organized as follows: the extent literature with regard to the
applications of social media into recall management is discussed in Section 2. Text
mining and social media data collection processes are explained in Section 3. The
results based on the social media data are exhibited in Section 4. Subsequently, the
managerial implications of this study are discussed in Section 5. Finally, the study
concludes with the limitation and future trend of research.

Literature review
Recently, social media platforms have been gradually used as directly communicate
approach to a large audience (Lee et al., 2015). Compared with traditional
communication channels, social media is relative easy to reach individuals and to
communicate effectively with wider community and to regain brand image (Long et al.,
2010). However, there are also issues related to loss of message control. Other than a
few limitations there are several benefits such as good communications with customers
post-crisis to restore customer trust (Tse et al., 2018). Widely used analysis in the social
media context is sentiment analysis or content analysis towards one specific recall event.
For example, Chen et al. (2015) analysed the number of Weibo posts, Baidu Indices and
mass media news before, during and post the “Kangtai hepatitis B vaccine crisis”. It
found that some false information and distorted media reports exacerbate public
perceptions on the event, and timely response should be implemented within the short
period before the high public attention arose. Besides, based on Twitter data of “Tesco
Horsemeat recall scandal”, Tse et al. (2016) use text mining method to analyse the
sentiment of public, which explores the content of social media data during one-week
period and reported the negative trends compared to the conventional channels.
Likewise, Tse et al. (2018) carried out another study based on the Facebook data of
“Tesco Horsemeat recall scandal”, which compared the social media data of customer
behaviours for the apology of Tesco. In pharma industry, Ledford and Anderson (2013)
conducted a content analysis via a CAUSE model based on the Facebook data of a
voluntary recall event. It states that customers will seek for information and support
from social media platforms and the focal company that is incompetent to design and
deliver clear and satisfied solutions. This information will impede the enactment
behaviour of some customers. In addition, the relationship between social media and
stock market performance has also been explored. Lee et al. (2015) stated that the high
frequency of social media activities of focal firms will mitigate the negative effects on
shareholder value, while Hsu & Lawrence (2016) found that the high-level engagement
on social media has no significant impact on the stock price during recall. Besides,
scholars also focused on post-crisis response strategy via social media platforms. Borah
& Tellis (2015) selected online chatter data from several automobile forums and indicated that the online chatter will aggravate significant negative effect on sales and apologizing advertisement also lead to negative effect on both focal and non-focal companies. Furthermore, there is a new trend that social media data have been used to identify potential safety hazards in a proactive way. Mummalaneni et al. (2018) analysed the review data of baby cribs from Amazon and indicate that some “smoke terms” that generated from sentiment analysis can be applied to explore potential safety hazards and thereby firms can conduct actions more proactively. In pharma industry, Hoang et al. (2018) studied the real-world Twitter data from over 10,000 users and found that social media data can be used to detect unknown adverse reactions, which support the research of Freifeld et al. (2014) in which they stated that Twitter data mentioning medical products and explaining their side-effects have concordance with the report from FDA.

Overall, there is extensive research covering product recall and the use of social media in product recall management. These researches focus more on an independent event (i.e. the Kangtai hepatitis B vaccine crisis), while the multiple-cases analysis of different recall events is not very clear. Besides, the study about non-toxic operations strategy is still scarce. In addition, as the second largest pharmaceutical market in the world, the research focus on China is rare, and hence the exploration on Chinese pharmaceutical recall management will be helpful.

**Methodology**

*Data collection*

This study chose Sina Weibo data as a research sample. We first collected the pharmaceutical recall data from Chinese CFDA official website. In total, there were eighty-five recall events were reported. Then the Sina Weibo posts and comments of each recall event were collected thorough Python 3.6. For each event the combination of “the name of company” and “recall” was set as searching key words and the time span of each event was defined as three weeks after recall announced. For each post, the information including the user name, content, number of likes, number of comments, number of reposts, time and URL were collected. Then, the top 10 hottest comments (that has top 10 highest number of likes) of each post were collected, which includes user name, content, number of likes, time and URL. In total, 20,592 Sina Weibo posts and 107,842 comments were collected. Because some recall events did not attract enough public attentions, hence the number of posts and comments were not adequate for our analysis. Finally, we decided to focus on twenty-one events which had more 60 posts. The details of the chosen events are shown in Table 1.

Data analysis

Text Mining (TM) is a widely used data mining approach that focused on high volume of textual data, which is robust for analysing the sentiment polarity of publics expressed in social media context (Tse et al., 2018). Generally, Machine Learning and Lexicon-based approach are two widely used methods for sentiment analysis. The lexicon-based method can directly assign the polarity of text content without any training database (Taboada et al., 2011). In this research, we used three lexicon-based libraries for simplified Chinese text processing (Tsinghua University Sentiment Dictionary, CNKI Sentiment Dictionary and Taiwan University Sentiment Dictionary), to conduct sentiment analysis to achieve the Polarity of public perceptions. Each post and comment got a number to reflect the polarity of content. Finally the cluster of post and comment were determined by the value (positive, zero and negative) and classified as positive, neutral and negative.

Findings

The main social media users of pharmaceutical product recall events

It is noteworthy that the pharmaceutical product recall events are now attracting far more volume of public attentions than five years ago. As the prevalence of social media, the information of recall events are now disseminating faster and broader than previous instances, which thus forced pharma companies to concentrate more on effective communications via social media platforms. For each recall event, we selected the top 30 hottest social media users that have the highest comments and reposts volume. These users were classified as six clusters, which are the government-led social media users, famous third-party social media users, local social media users, Internet Celebrities, healthcare industry related social media users and other users. Figure 1 illustrated that
there were a few government-led official accounts and famous third-party mass media active accounts that was established before 2015. At this stage, the most common users are private Weibo accounts with relatively low followers. Given the low level of impact of these private users, the other Sina Weibo users did not put too much emphasis on these recall events. As shown on Table 1, the five recall events from 2011 to 2012 had low volume of comments and almost zero-level reposts. Afterwards, more locally media accounts (i.e. local newspaper account, local government account, etc.) were engaged in the post-recall period between 2015 and 2016, especially for some regional recall events without national impacts. Subsequently, an increasing number of more authoritative and famous third-party national media (i.e. Global Times, Financial Network, Southern Urban Daily, Sina Finance, etc.) Weibo accounts that have higher influence on the publics were becoming the major participants of recall events. In addition, the followers of government-led social media accounts grew significantly. For example, the CCTV News has over 83 million followers and the People’s Daily has over 88 million followers. Once the pharmaceutical recall events have been commented by these accounts, the public attention picks up at the growth is exponential.

![Figure 1 The classification of Top 30 information leaders of typical recall events](image)

To understand who the “trendy” was during post-recall period, this study analyzed the frequency of those 630 users whose Sina Weibo post had highest number of comments and reposts. Overall, the Top 20 information leaders were mainly government-led media and national-level third-party media accounts that have millions of followers and have significant impact on public perceptions. Although there were two healthcare professional accounts and four local media accounts, the audiences of them were relatively narrow.

The daily change of public attention

To explore how the public attention fluctuated during different recall events, this study analysed the number of daily comments for three weeks post-recall period. We classified all twenty-one recall events into four main categories, which are raw material related recall event, low public attention recall event, middle public attention recall event and high public attention recall event. In terms of the first cluster (shown as Figure 2), despite with different attention-degree, both of the raw material recall events did not attract public attention for a long time. After first two or three days’ heated discussion, the publics always shown their tolerance and blame less for the involved companies. After one week, the public attention level was almost back to zero.

![Daily Comments of Raw material related recall event](image)

**Figure 2 Daily Comments of Raw material related recall event**

As for the low and medium public attention recall events, after recall announced there was always a two to four days “buffer period” for pharma companies to deal with the explosive public opinions from social media. In terms of some events without serious hazard (i.e. Case 1, Case 9, Case 13, Case 16), publics will not have further discussions on these topics afterwards. However, for those events with safety hazards and high public involvement, the follow-up
inspection reports from Chinese CFDA or punishment via other government sources would then generate a second peak (i.e. Case 2, Case 4) around one week after recall announcement. Afterwards, the public attentions will back to zero level after two weeks.

However, in terms of the events caused serious safety and high public concerns, the extension of the time period was much longer than other events. Even after three weeks, the daily average comments were still around 1,000. Although there may be two to three days buffer time for pharma companies to provide positive reactions, once involved in this kind of event, they have to spend substantial amount of time and resources to flee from the mire.
The time series analysis of public perceptions: the Changsheng BioChem Vaccine case

To explore the changes of public perceptions more in-depth, this study chose a latest case, Changchun Changsheng BioChem vaccine recall event, as an example to explain how the polarity of public perceptions changes during the post recall period. As shown on Figure 6, there were seven main events happened. After CFDA published the recall announcement on 15th July 2018, Changsheng started the recall on the second day and the public perceptions become extremely negative. On 17th July, Changsheng published a statement that confirmed the production of defective vaccine has been stopped and expressed the apology to the publics. However, the publics were not satisfied with their response, which is in line with the negative polarity data at point 2. Then on the fifth day, several famous media released news that the recall was reported by insider staff and further inside information was published, and hence the publics expressed more untrustworthy and anger on the company, then the polarity decreased again. Afterwards the President Xi and Prime Minister Li stated “the recall event must be seriously investigated and corrected” in succession on 23rd July and 25th July and the Chairman of Changsheng and other senior managers were arrested. Therefore, the public opinions were to some extent recovered during these days. Then as the investigation conducted, more news reported the staff of Changsheng meant to destroy the evidence of sixty hard disks that recorded the production information, thereby the public opinions back to extremely negative again. After two weeks, the investigation was finished and Changsheng got very serious punishment, and meanwhile Prime Minister Li stated the long-term vaccine regulation and traceability system must be established. Those reactions again regained the trust from publics.

Discussion

First, for the social media users, as mentioned above, the major information leader are now becoming authoritative third-party media users. On one hand, the reliability of news is better than past and less irresponsible “toxic” small media can distort the public opinions. On the other hand, it means the fully control of information post recall is more unprocurable. For those pharma companies still tend to manage all information sources and try to delete relevant negative news as conventional way are now becoming more and more difficult. Therefore, Chinese pharma companies must rethink their media relationship strategy. A long term social media relationship should be established before the product-harm risks.
Second, time to recall is a crucial factor that directly influences the response of publics. According to current Chinese recall regulations, the time limit of recall is in accordance with the class of recall (Class I within 24 hours, Class II within 48 hours and Class III within 72 hours). However, this time limit in China is more like the time to stop the circulation of products from market. According to the results, most recall events had a two to four days “buffer time” for companies to conduct effective response activities before the public opinions become worse. However, few pharma companies have persuasive responses during this time. Another time point is around one week when the government always publishes follow-up report to explain the investigation and corrective actions, especially for serious events. If the pharma company could not achieve effective management before the first time limit, they must make full use of this one week to establish a responsible company image, otherwise they will be more passive and incur substantial number of negative comments afterwards.

Besides, as can be seen from Figure 6, the polarity of daily sentiment is able to reflect the changes of public perceptions caused by different key issues. It is noteworthy that simple apology to the publics may not as effective as previous time. Compared with other industries, pharma products are closely related to safety and health of all human beings. Therefore, the public concerns of potential hazards may weaken the effectiveness of apology. In addition, due to the extremely poor performance of Chinese pharma companies in the previous time, publics will not be satisfied with simply apology response strategy. Pharma companies should provide more details about how to collect defective drugs and how to compensate involved patients.

Overall, pharma operation managers can benefit from the evidence-based guidelines to integrate social media context into post-recall communication strategies. First, this study helps pharma companies to identify “toxic” information agents of recall events and thereby establishing close relationship with them on the long run. Meanwhile, pharma managers can understand the importance of non-toxic “buffer time” and conduct more effective actions during “non-toxic to toxic” transition time and hence mitigating potential impacts.

**Conclusion**

Through the analysis of Sina Weibo data of twenty-one pharmaceutical recall events, we found that: 1) the major social media information leaders of drug recall events are now mainly authoritative third-party media, which thus make pharma managers more difficult to fully control the negative information post-recall; 2) except for those extremely serious product harm-crisis, the social media public opinions of most recall events will gradually degrade within two weeks, while pharma companies still need to make full use of the “buffer time” to mitigate the explosion of social media attentions; 3) the apology strategy is becoming less effective in current years, and hence more proactive response actions should be considered.

The limitation of this study located on two aspects. First, all these companies are only based on Chinese background, the geographical differences should be considered to compare the other social media from different perspectives (i.e. Facebook, Twitter). Second, given this study is a retrospective study that collected historical social media
data, a part of data may be deleted by the users, which thus affect the accuracy of data analysis.

Abstract

The ways of coping with the complexity of implementing lean production in Multinational Corporation diverge. Successful knowledge transfer within corporations’ network of production plants is of major importance. One way to roll out programs with changes rapidly is through top management commitment. The paper reports from an industrial case study exploring the characteristics, as well as issues and success factors, of a roll-out program to implement a standard. Important factors were identified, such as early involvement of stakeholders, type of knowledge transferred, involvement at both group and individual level, and to secure external deliveries prior to initiation of the program.

Keywords: Operations/production management, lean management, lean production

Introduction

The last two decades, many multinational corporations (here, MNC) have expanded their manufacturing footprint by increasing their number of production plants worldwide. There are numerous benefits with MNC, such as market presence, the ability to invest and the diversity of knowledge within the corporation. However, new challenges may also come with an expanding manufacturing footprint. For example, transferring knowledge within a MNC could be challenging due to complexity caused by variation amongst the production plants (Jacquier-Roux and Paraponaris, 2012; Boscari, Danese and Romano, 2016).

High level decisions may affect the production system at several production plants in various ways, which increases the complexity to implement, for example, lean practices in MNC (Bellgran, 2018). Considering that the fundaments of implementing lean production may be a strategy of survival on the world market, large investments of
multi-plant improvement programs are of major importance to be successful. Moreover, unsuccessful programs could lead to reduced competitiveness. According to Netland et al. (2014), limited available research within the field of improvement programs makes it challenging for industry to get guidance to manage and design them successfully (Netland and Aspelund, 2014).

The research within the field of lean implementation as a concept and specific lean practices, both theoretical and empirical, is extensive. Despite this, few examples of successful implementation of the concept outside of Japan are presented due to the challenges faced in the deployment of lean (Jadhav, Mantha and Rane, 2014). Some papers suggest sequences in which lean practices should be implemented, with the intention to guide towards a successful implementation (Womack and Jones, 2003; Hines, Holweg and Rich, 2004; Anand and Kodali, 2010). But, lack of a consistent lean implementation framework with guidelines or a process is among the issues challenging lean implementation success (Bhamu and Sangwan, 2014). There is no well-known best way to implement lean production. Although examples of different conditions fostering success of lean transformation found in literature are; top management commitment, early employee involvement, employee autonomy and information transparency of achieved benefits while some issues being, for example, improperly planning prior and after the implementation (Achanga et al., 2006; Scherrer-Rathje, Boyle and Deflorin, 2009; Bhamu and Sangwan, 2014).

In industry organizational systems are created for implementing lean where lean practitioners function at different hierarchy levels involved in different levels of business process management. There are various ways of implementing methods and standards in the organization. Often standards are developed globally and gets piloted at a production plant prior to a broad roll-out in the corporation. This can be beneficial in terms of efficiently targeting a wide range of production plants, but can also create resistance and decrease engagement when standards are not created locally at the production plant.

The way of achieving lean production consist of several attempts of implementations and rolling out new improvement programs to develop the current production system. Despite the vast literature on lean implementation, there is limited research of effective processes of rolling out changes of existing lean practices. One exploratory study presents seven roll-outs in production plants of different MNCs (Secchi, Raffaele; Camuffo, 2016). However, these roll-out processes were studied at case companies with no previous experience in lean production.

Successful knowledge transfer within corporations’ network of production plants is of major importance. The knowledge transfer is considered as a process that is dependent on the nature of knowledge and the ways of communicating (De Luca and Rubio, 2019). There are two types of knowledge; explicit and tacit (Nonaka and Teece, 2001). Explicit knowledge can be expressed with words and numbers, thus can be shared through for example, manuals or standards. On the other hand, tacit knowledge is difficult to explain with words and is very subjective, which makes it hard to transfer to others. With the aim to reach a wide group of plants at a MNC in designing improvement programs there might be lack of understanding in type of knowledge to be addressed, and perhaps tacit knowledge is neglected in roll-out programs.

This research aims to describe the issues and success factors identified when rapidly rolling out an improvement program with the purpose of changing a lean method by adapting global standards of the MNC. More precisely, the research questions to be answered in this paper are:

RQ1: What characterises a rapid roll-out process when transferring a standard within a multinational corporation?
RQ2: What are the issues and success factors for a rapidly roll-out process when transferring a standard within a multinational corporation?

Methodology
The paper sets out to explore and describe characteristics of a rapid roll-out of a lean method change. A rapid roll-out is here interpreted to be a few months targeting an entire production plants consisting of several levels of management and business units. In the context of this paper, the term “lean method change” is defined as the objective of the improvement program aiming for transferring knowledge from global “best practice” of the MNC to one of the production plants. The change is considered to be minor and the lean method is already a part of the current lean practice. A minor change can be, for example a different approach in the method, or a template modification, hence the aim is to improve the use of the method.

This study has the perspective of the process of transferring knowledge within multinational corporations, from global level of the corporation by adapting a global standard and transfer it further to one production plant. By following the roll-out program from the point of the decision by top management to the implementation at the shop floor, an in-depth case study approach was considered suitable for the purpose. It follows the preconditions of a case study, as presented in (Yin, 2009).

The roll-out program was initiated by top management at a multinational corporate production plant. A representation of all levels of the hierarchy within the production plant was part of the study. The roll-out program was followed at one of several business units (here called “Unit X”). The management consisted of four levels, included with top management. Involved lean practitioners were functioning at three levels: global, local-central and local-business unit. Data was collected through semi-structured interviews, on-site observations and documentation from different corporate functions. The interviews started with an initial protocol and were tailored to fit specific the interview setting; notes were taken both during the interviews and the observations.

The analysis was performed utilizing mixed method in two steps. At first, triangulation of data was made of the interview notes, field notes and documentation in order to verify the description of the roll-out program. Secondly, a comparative analysis was done of the planned roll-out and the actual execution of the program. The subjective views on the success of the roll-out was measured at the company by their achievement of set milestones and amount of individuals receiving training.

Theoretical framework
Lean production is a concept inspired by the Toyota Production System (TPS) where the fundamental purpose is to eliminate waste of the value stream of products, including the supply chain. With the main focus on bringing value to the customer the essential purpose of implementing lean is for some industrial corporations a way to stay competitive (Netland, 2016). There is comprehensive literature about the lean philosophy and principles, and the tools and methods supporting them (Womack and Jones, 2003; Hines, Holweg and Rich, 2004; Liker, 2004; Shah and Ward, 2007). Even though lean as a concept is easy to grasp, it is difficult to implement for various reasons. Previous research (e.g. Sherrrer-Rathje et al. (2009)) describe these challenges by highlighting failed attempts to implement lean practices at companies with no previous experience of lean. The challenges with implementing lean production can also be reflected in the study of Netland (2013) describing the occurrence of tailored corporate specific production systems, by which a production corporate is adapting the production system based on
TPS. This may be result of issues to adapt and sustain the effects of lean practices to the corporations’ unique contexts.

Based on the current challenges of implementing lean production in multinational corporations the capability of creating value depends partly on the transfer of internal and external knowledge to the local context. The process of rolling out improvement programs based on adapting knowledge from one part of the corporation to another can be compared to the knowledge transfer process. Moreover, when a production plant adapt a global standard and use the skills and capabilities of global practitioners in the MNC the knowledge needs to be transferred from one part of the organization to another. As described by Nonaka and Takeuchi (1995), the transfer of knowledge is in general a very challenging assignment because knowledge is not tangible and usually get defragmented across the organization. Also described in literature, lean transfer is a complicated process due to the combination of for example technical and analytical tools (“hard practices”), and team building and employee training (“soft practices”) (Shah and Ward, 2007; Danese, Romano and Boscari, 2017).

Findings

Context of the production plant

The roll-out case was initiated by the top management team at a production plant located in a western country, which is a part of a multination corporation. The corporation is active within the pharmaceutical field which includes development of new medicines as well as production. With more than 60,000 employees at 30 different production plants located in 18 different countries, the production plant in this study is one of the largest.

The organization has lean practitioners’ positioned both on a global and local level. Locally the structure can differ between plants depending on the context. The global lean practitioners have responsibility to lead group-wide improvement programs targeting several production plants for example assessment programs or developed global standards. Some standards are considered mandatory and others optional for the production plants to adopt. At the production plant in this study there are lean practitioners at a central level supporting the entire plant (“central lean support” in Figure 1). Furthermore, other lean practitioners support the management group locally at the seven business units of the plant (“local lean support” in Figure 1).

Figure 1: Overview of lean practitioners’ organizational structure
The lean practitioners on local-central level has often responsibility in the development of business processes through global and local networks. In practical means that imply knowledge transfer between practitioners in binary directions. The aim of process networks is to constantly develop the process to the “best practice” of the corporation.

In this context, a group-wide assessment program identified gaps of desirable capability in a certain lean method. The assessment was partly based on adoption of global standards. There was a deviated view among lean practitioners whether the production plant complied with the mandatory global standard. This was one of the triggers for the top management to decide a rapid roll-out program aiming the entire plant.

*Describing the planned roll-out*

The roll-out program consisted of three components, see Table 1 and Figure 2. The first component, an e-learning targeting the entire site on individual level. Purpose of the e-learning was to create awareness, provide interactive training and enable follow up of the training. The second component was training by global lean practitioner to all lean practitioners at the production plant and the top management. The training was focused on both the purpose of the roll-out, and knowledge transfer of the global standard. The third component was the change from current template to the new global standard template.

All components were ought to be rolled out rapidly, within a few months, to the entire plant (see left in Figure 2). The roll-out program was planned and lead by top management starting with component 2, training of the highest level of management. Parallel to component 2 shortly thereafter component 1 should be available and target individuals. Early on at the decision stage some stakeholders were involved; global and local lean practitioners (both central and at business units).

The purpose of training (component 2) was to involve all managers with the starting point of top management, which in turn trained the next level of management with optional degree of support of lean practitioners at respectively business unit (see Figure 2).

The actual roll-out

The actual roll-out of the program, (see right in Figure 2), did not completely compile with the planned. The major deviation was a delay of e-learning (component 1). The e-learning could not be rolled out due to delays of translation of global learning material to the local language. Some frustration and confusion was noted due to challenges with scheduling training time for operators when the e-learning was not available on set time. Likewise, information of coming changes in template spread in the organization and entailed increased pressure of managing questions before received information and training. Moreover, compromised communication with external parties was the reason of the delay.

The training of all management levels were executed according to set deadlines. So, managers of all business unit were provided with information of the change and need of support by lean practitioners varied among them. At “Unit X” the management team firstly used provided information, and upon need for practical training adjusted information material to the local context. Prior to management meetings the lean practitioners at Unit X had a preparative training session with support of central lean practitioners. One of the local lean practitioner supported to a major part by training the lower management levels. In terms of optional design of the roll-out at the business unit’s, only deadlines were decided by top management. In addition, a new component was developed (called “Clinics” see Figure 2). Whereas the purpose of hands-on training by all lean practitioners with new template. Held by the global lean practitioner at two occasions and was optional to attend.

Above all, despite clear definition by top management for successful implementation the actual roll-out program was considered as successful in the means of all managers being trained (component 2). Furthermore, after 20 weeks 57 % of all employees received training, which was considered acceptable.
During the training of the local lean practitioners, it came across that there were contradictions between the global and local views of current ways of managing the particular lean method at the production plant. It also came across that the purpose of the rapid nature of the roll-out was not well understood and there was some degree of lack of transparency in the communication from top management as to what the decision was based on, for example that early inclusion of stakeholders and comparisons of old template with the new template was done.

The emphasis on new template (component 3) was predominant in all levels of lean practitioners. During discussions regarding issues around the decisions of mandatory and optional standards on a global level the feeling of “loss of power” was expressed for example, one central lean practitioner commented:

“I have the feeling that the global people take over”,

Then again, unexpected changes of opinions were also identified. Some individuals changed their view of global and local collaboration.

The new template was perceived as complicated and difficult by lean practitioners, managers and other support functions. A reaction to the rapid roll-out was by one lean practitioner exemplified in this quote:

“I do not understand what we put energy on. The good thing is that they [top management] took the decision and they are responsible for it... but the template is not going to solve the problem”.

Yet, changes in the view regarding the template were noted over time, for example, several of the early involved persons from different functions could after approximately
3 months agree on that the new template is an improvement compared to the current template. One local lean practitioner said:

“At first, I thought ‘No!’ But I guess I am over that phase in my change curve and I think the new template is better.”

This got confirmed by several other persons from other business of units. With this in mind, the reactions of operators were positive and realistic in the means of that they could see benefits at the initial training session of the new template and understanding that supplementary training is needed. Thus, responses to change of template were perceived as more positive in contrast to the ones of management level. Exemplified here after a training session of management at Unit X:

“I experienced that they over complicated it .. the new template is certainly messier, but they had the same reaction as I did in the beginning”.

In combination with the frustration of the rapid roll-out program it was mentioned several times that top management being responsible for the decision was viewed as positive in the motivational aspect of transferring the knowledge to lower levels in the organization.

Discussion

The purpose of the roll-out program was to increase the capability concerning a specific lean method and adopting to a global standard seen as “best practice”. The combination of components 1-3 (in Table 1) had the intentions to transfer knowledge to individual and group (lean practitioner and management) levels of the organization. This was performed through a global lean practitioner and global standard in writing as the transfer agent. Explicit knowledge was transferred in every component; global learning material in e-learning, global learning material in training of top management and lean practitioners and global standard in form of a new template (see Table 1). However, with major emphasis on adapting to a global standard (i.e. explicit knowledge), component 1 and 2 in the roll-out program was also dependent on tacit knowledge. Moreover, the tacit knowledge of the global practitioner was of use in sessions in form of discussions and interactive hands-on training created in form of “clinics” (see Figure 2). The flexibility of each business unit to design the roll-out further could be seen as a strength to create new formats of training if needed even though it is not predefined by top management. Suggested here is a new component “Group level- Tacit knowledge creation” to be considered (see Figure 3). Even though the lack of outspoken intention to transfer the tacit knowledge it is seen as a success factor to give the business units autonomy for a part of the roll-out program. However, the success of the program was not measured through gained capabilities but received training. It could be argued the roll-out program was based on management of information rather than knowledge.

The roll-out program is not considered successful in the perspective of accomplishing a transfer of all components to set deadlines. The major deviation was the delay of component 1, e-learning to all individuals of the production site. However, the intention was to create awareness and be support through the roll-out program, yet did not stop the progress of the other components. Despite the clear issue with the delay due to external parties, such as translation of documents to local language, it was a factor of success to design the program to not have dependent components in order to enable the intensity of the roll-out. Likewise, the e-learning was built to be interactive to train individuals by using explicit knowledge but information was needed to be typed in and therefore categorized as “tacit knowledge creation” and is proposed to be a later component of the program (see Figure 3).
One approach to the difficulties to roll-out programs broadly, and also quickly, can be to build the roll-out program addressing these different success factors: means of transferring the tacit knowledge (e.g. global practitioner in MNC), group level as well as individual level, understanding of the transferred explicit knowledge and creation of own tacit knowledge.

Several individuals of those involved early in the program stated an individual change after some time regarding the new template, thus could see benefits with the global standard. That is an indicator of the explicit knowledge in component 3 was not adequate and the other components was needed as a part of the program (see Table 1).

By rapidly rolling out a program widely at a production plant that leads to change may compete with other ongoing activities. If the time required for the program does not match with available time both frustration of involved actors, and decreased effectiveness of the program can occur. Thus, the frustration and resistance observed could reduce people’s commitment (Senge et al., 1999). Although the clear top management commitment in the roll-out program is seen as a success factor due to that it was a clear statement of importance of the specific capability, one should address the risk of organization inertia if multiple programs or activities are ongoing simultaneously.

Conclusion

Recommendations in case of future rapid roll-out programs is to involve stakeholders early, consider type of knowledge to be transferred when designing the program, involve at both group and individual level and secure external deliveries and communication prior to initiation of program. The findings contribute to knowledge of how to improve the design and planning of roll-out programs initiated by top management of production plants belonging to a MNC. This is of relevance to industry, because rapid roll-out programs locally at single production plants can be triggered as result of group-wide MNC improvement programs. The key success factors for a rapid roll-out process can be used prior the decision for more sustainable effects. Such support affects the quality of the roll-out process, for example by reduced resistance level and less frustration. Likewise, the method of rolling out programs rapidly should only be wisely considered dependent on type of knowledge that should be transferred. This in turn enables corporations to deliver better value to their society of end customers by the potential performance gains of successful rapid roll-out processes, in the field of production management in general and lean management in specific.

Limitations/implications

This study was not designed to follow all business units at the production plant. There were variety among the production units in the roll-out approach locally. Hence, this
study is only capturing a smaller context of the production plant. Also, due to that the roll-out program is still ongoing there is minor data from shop floor level which may weaken the operational point of view. Furthermore, effects on actual business results cannot be stated at this point and needs to be followed in a longitudinal study.

Abstract

Whereas systematic literature reviews and systematic reviews have become common practice for the domain of operations management and supply chain management, guidelines have been confined to which steps and processes should be followed; the aim of this paper is to not only discuss some of the steps in more detail, but also to provide guidelines to what constitutes a high-quality literature review, whether systematic or not.

Keywords: Literature reviews; operations management; supply chain management; systematic reviews.

Introduction

Whereas literature reviews are part of any scholarly study into operations and supply chain management, guidance on how to conduct literature review is relatively scarce, except for what are called systematic reviews aka systematic literature reviews. There is some general guidance on how to conduct literature reviews, such as Green et al. (2006), and protocols for literature reviews (for example, Cronin et al., 2008; Tranfield et al., 2003), some of them directed at operations management, for instance, Thomé et al., (2016), albeit that the latter is a re-iteration of techniques for systematic reviews derived from practices in the domains of medicine and nursing. However, based on recent submissions to ranking journals (e.g. Journal of Manufacturing Technology Management) and practices found in published literature reviews, there are points that deserve attention by authors interested in publishing high-quality literature reviews.

Objectives of Paper

How to conduct an appropriate literature review is a contentious point of discussion. There are those that advocate systematic reviews and systematic literature reviews. For instance, Seuring and Gold (2010, p. 552) advocate the use of content analysis to this purpose, but also note that this often falls short of expected reporting standards in the case of supply chain management. Contrasting those favouring there are calls that systematic approaches to literature reviews are limiting useful outcomes. For example, Boell and Kecmanovic (2010; 2015) demonstrate the limitations of systematic approaches to literature reviews that have become more popular; instead they see literature reviews as a creative process where the state-of-the-art knowledge captured by literature is constantly...
assessed on its value. However, both views indicate that literature reviews should be capturing extant knowledge in a meaningful way and appropriately reported, including the rationale for the approach.

**Scope and Outline of Paper**

To this purpose, this paper will offer guidelines for what is to be expected from high-quality literature reviews; these guidelines can be used by doctoral students, early career researchers, academics and members of editorial boards to conduct and to present these reviews. These guidelines should be read in addition to existing guidelines. The scope of the current paper does not include propositional papers, because these serve a different purpose.

This paper will start with how literature reviews contribute to the rationale and content of empirical studies. This leads to consideration of quality criteria for literature reviews. Afterwards different types of literature reviews are presented related to these quality criteria. This will be followed by how the contribution to knowledge can be identified. Some practical issues are also highlighted before the concluding section of the paper.

**Positioning Literature Reviews**

Literature reviews are not just a matter of doing them, but play a role in the research process and the design of research studies; however, particularly for operations management, much attention has paid to guidance for specific research methods, while somewhat neglecting the role of literature reviews contributing to research processes and enhancing the quality of studies. A case in point is Forza (2002, pp. 160, 187) who refers to literature to be consulted about content validity, constructs of surveys and theoretical underpinnings, albeit detailed guidance is missing. The same assertion, including the consultation of experts, already appears in Flynn et al. (1990, p. 266), when advocating empirical research for operations management in general, and Malhotra and Grover (1998, p. 412) specifically for surveys. In the same vein, McCutcheon and Meredith (1993, p. 250) indicate that postulates should be derived from literature for case study research. Stuart et al. (2002, p. 423) take it further by stating: ‘the implication we draw is that better (i.e. publishable) research papers start from a broad literature base.’ This all indicates that the use of literature should aim for achieving content validity ex ante empirical research methods and development of practical applications; therefore, the quality of literature review determines the suitability for this purpose.

However, literature does not only play a role for achieving content validity in empirical studies, but should also be used for assessing external validity. For instance, Voss et al. (2002, pp. 216–7) advise to compare emergent conceptualisations from case study research with existing scholarly knowledge. A case in point is Dekkers (2018, pp. 272–3) who compares methods used for designing organisational structures based on group technology in three cases with five reported cases in literature; this provides evidence for da Silveira’s (1999, p. 470) propositional parameters that determine the choice of method for cell formation. This illustrates Voss et al.’s point about comparing conceptualisations from case studies with related ones found in literature, thus increasing external validity of findings from empirical research.

Furthermore, also for achieving rigour and reliability scholarly knowledge should be integrated in a study. A particular point is the design of a study, where beyond generic guidance for detailing a research method, specific points could be addressed. A case in point is the use of focus groups in empirical studies. In addition to generic guidance found in books, such as Cresswell (2014), specific publications have addressed how to
enhance this research method in order to achieve more reliable outcomes. For example, Kidd and Parshall (2000, p. 298–9) present recommendations for the recording of focus groups, the number of researchers per focus groups, their roles and the checking of any tentatively identified issues for confirmation or clarification. Such detailed guidance for a specific derived from a literature review will lead to increasing the rigour and reliability of a specific empirical study.

**Assessing Quality of Literature Reviews**

In addition to literature contributing to the construct validity, external validity, and design of research methods for empirical studies, quality criteria for research also apply to the literature review itself; an issue we intend to explore now. A starting point is that most commonly literature reviews can be viewed as qualitative research. There are many publications addressing different aspects of the quality of qualitative research, with Mays and Pope (2000), and Walsh and Downe (2006) being publications in point; note that many of these writings are set in different disciplines, because looking into the quality of qualitative research in operations and supply chain management is mostly limited to case studies (e.g. Seuring, 2008) and action research (for example, Näslund et al., 2010). If a literature review is considered akin to qualitative research, then there is abundant writing available ranging from discussing criteria (for instance, Tracy, 2010) to reporting standards (e.g. O’Brien et al., 2014; Tong et al., 2007). Setting aside the worthiness of the literature review in these publications for later, conventional criteria for qualitative research include internal validity, external validity, reliability and objectivity (Guba and Lincoln, 1989 cited in Halldórson and Aastrup, 2003, p. 323) and in similar vein, objectivity, internal validity, external validity and utilisation (Miles and Huberman, 1994, pp. 277–80). However, a literature review is different from qualitative research in terms of data collection and analysis. Therefore, some criteria or only aspects of criteria for may apply to literature reviews; these will be discussed next to provide guidance.

With regard to validity, the literature review needs not only to provide a close examination of retrieved publications, but also itself to provide a coherent skeleton from a critical perspective. In this respect, for qualitative research in logistics, Halldórson and Aastrup (2003, pp. 323–4) posit that craftsmanship and trustworthiness play a major role in creating validity. According to them, craftsmanship refers to checking, questioning and theorising (ibid., pp. 323, 328–9). Applied to a literature review this means that retrieved studies should be scrutinised on their factual contribution and placed in the wider context of a literature review. A case in point is Dekkers et al. (2013, p. 317), when they come across the study by Antonio et al. (2007) on the impact of product modularity on competitive capabilities and performance of manufacturing firms; they duly note the authors’ circular reasoning for the origins of modularisation and the performance criteria used in the study. This also implies that research methods used in studies should be evaluated on their appropriateness. One way of doing so in a literature review is by triangulation, a common method for assessment in qualitative research (Mays and Pope, 2000, p. 51). By comparing two or more publications with different research methods or with different samples, an appraiser will look for patterns of convergence or divergence. The notion of trustworthiness adds further depth to a literature review, using Halldórson and Aastrup’s (2003, p. 326–9) description. Credibility, one of its qualities, means that the context of relevance to the literature review is used explicitly to evaluate studies. Such is explicitly stated by Mazzocato et al. (2010, p. 376) in the rationale about lean thinking for health care presented in their introduction and later (ibid., pp. 377–8) for the context of specific health care provision when evaluating other studies. In this reasoning, also
transferability as quality of trustworthiness is found in terms of whether findings from one context can be applied in other contexts. Such would require considering isomorphism (Dekkers, 2017, p. 64; Halldóron and Aastrup, 2003, p. 323) and levels of abstraction (Dekkers, 2017, pp. 43–52; Timpf, 1999). This means that the basis for high-quality literature reviews is found in craftsmanship (checking, questioning and theorising), searching for triangulation, consideration of context and abstraction from the perspective that a literature review is a critical work; see Table 1 for an overview and more detail.

Occurring as a second main criterion for literature reviews, derived from qualitative research, is reliability or dependability (the latter related to trustworthiness as quality of qualitative research). Reliability relates to the quest for invariance (Halldóron and
Aastrup, 2003, p. 328), which in the case of a literature review, principally tells that outcomes should be the same, no matter the evidence base that is accessed and the method for the appraisals; subtly different, dependability considers traceable invariance. This quest for invariance can be considered akin to the principle of theoretical saturation (Steenhuis, 2015, p. 356) for case studies; invariance for literature reviews occurs when no longer inferences and conclusions change when subsequently publications are added to the literature review. To avoid complacency, craftsmanship in literature reviews includes searching for publications with extreme and deviant findings, thus meeting the subcriterion for falsification for qualitative research (Halldórson and Aastrup, 2003, p. 328–9). Consequently, this indicates that a literature review should indicate whether outcomes of its appraisal would benefit from further studies applied to similar samples (confirmatory research), different samples (either generalisation or instantiation) or different research methods (triangulation).

Following another, fourth criterion – confirmability – Halldórson and Aastrup (2003, p. 328) suggest that data should be tracked back to their sources and an audit process. Normally, such should be made evident in empirical studies. However, for the case of literature reviews, this could be seen as not only accurately citing or paraphrasing sources, but also providing coherent reasoning. In addition, this criterion could also be asserted by external reviewing; in the case of literature reviews, this could be ‘independent’ academics reviewing a literature review, but also reviews and feedback from seminars and conferences. Evidencing how reviewing and feedback has shaped a literature review may be a point to be addressed in publications, but is hardly common practice, though worthwhile considering.

Particularly systematic approaches to literature reviews add rigour as an additional criterion for quality. In these approaches, called systematic qualitative literature reviews and systematic quantitative literature reviews by some (e.g. Green et al., 2006, pp. 145), the way publications are evaluated is driven by a protocol and the analysis follows also pre-set patterns. It should be noted that Boell and Kecmanovic (2010, p. 131; 2015, p. 169) advocate that systematic literature reviews are confined to clearly delimited topics about which sufficient publications are available; for the latter, it may be noted that this will most likely depend on how much robust evidence is available. This means that although rigour can be added by developing a protocol for a set review question, for generic literature reviews this may be too restrictive for developing research questions during process of the literature review.

**Types of Literature Reviews**

In addition to considering how criteria can be used to improve the quality of literature reviews, another question what different types of literature reviews are. It ranges from limited literature reviews, in terms of number of publications, to extensive literature reviews. The first can commonly be associated with statistical analysis and econometric modelling, in which authors get quickly to the point about the usefulness of their research and then go on with the empirical study. Typically, these include also assessment for the rationale of variables to be used. Examples of this category are Çankaya et al. (2019) and Green et al. (2019). More extensive literature reviews include both the pros and cons of theories, conceptualisations, methodologies and methods to arrive at an evidence-based position to what extent there is a gap in scholarly knowledge and how to advance research. Instances of extensive, informative literature reviews are Boer and Boer (2019), and Newman (2003). At the extreme end of the typology are the systematic literature reviews and systematic reviews; the former follows a systematic approach to a review.
question, whereas the latter is aiming at the impact of an intervention, thus having a narrowly focused perspective. Cases in point of these systematic approaches for the operations and supply chain management are Colicchia and Strozzi (2012), and Stone (2012). The practice of limited literature reviews may be acceptable for some research, but our attention in this paper has gone and will go to what could be classified as extensive literature reviews that are not restricting the rationale to publications that favour a certain stance or specific study.

In this typology, the criteria for the quality of literature review should be applied in a different manner to each archetype. In a limited literature review the aim is identifying relevant variables for constructs and causal relationships that are of interest. Meeting the quality criteria for this type of literature review means investigating ‘questioning’ and ‘theorising’, searching for falsification, evaluating triangulation and looking at contexts of specific (empirical) studies. When undertaking an extensive literature review such includes also the consideration of abstraction mechanisms – classification, aggregation and generalisation –, and investigating for invariance.

**Identifying the Contribution to Knowledge**

Particularly, with the number of submissions of systematic literature reviews increasing, it is important that the contribution to academic knowledge is ensured. Some submissions in their search of literature find other existing reviews, sometimes published a few years before, which arrive at similar findings, and despite such claim their contribution as being original and novel. This implies that any literature review should start with positioning existing reviews on the topic or related to the topic: what will the literature review offer what others have not yet looked at. This also implies then that the review questions should be different from existing writings. Such should be assessed a priori, and, therefore, part of the introduction of a literature review.

Furthermore, a literature review should not be focused on a single outcome or single model. In general, outcomes of literature reviews should cover a wide range of topics and pinpoint implications for further studies. An example of this practice is found in Salgado and Dekkers (2018) providing a range of topics, and guidance for doctoral students, early career researchers and research programmes. This implies that the a priori contribution to knowledge should be evaluated and presented ex post.

**Some Practical Points for Literature Reviews**

In addition to the quality criteria for literature reviews, there are some practical points that emerged from reviews of submissions to a variety of journals. These points also reveal practices for writing literature reviews (and what should be avoided).

**Understanding of Conceptualisations and Key Terminology**

In addition to demonstrating knowledge about the state-of-the-art in a domain, conceptualisations and key terms (and their alternative formulations) should be understood. A recent example is a study that looked at the term ‘supply chain management’ only, but when the reviewers extended the search with ‘supply chain’ and ‘supply network’ it appeared that others already described the outcomes of the submission. Such examples show that the actual outcomes of a literature review are dependent on the formulation of keywords and knowledge about terminology in a domain.

Furthermore, key conceptualisations and key terms should be defined. A case in point is the term ‘business competitive landscape’ appearing as a key concept in a submission to a ranking journal; however, this term is hardly used by other publications and never in the...
core of their argumentation. In the submission no definition or description is provided, this leaves open what is meant with this key term and also leads to questions about the empirical research that was undertaken.

Close and Critical Reading
Such extensive literature reviews consider evidence or reasoning presented in other papers rather than just lifting statements from publications. This should be reflected in adequate paraphrasing. Inadequate paraphrasing happens frequently. For example, Dekkers and Kühnle (2012) are paraphrased by de Moura and Botter (2017, p. 883) for the following three statements:

• Factors such as financial sustainability, ways of relating to their supply chain and customers, reliability and recognised quality of products and service are key points that shall be taken into consideration when making strategic decision for a company to become globally competitive.
• Thus, it is essential that companies make investment as a way to stand out from competitors and gain recognition.
• It is also essential to integrate innovative business strategy of a company and its partners.

However, none of these statements can be traced back to the actual text nor can they be considered interpretations of it. This shows that paraphrasing must meet a few criteria to be meaningful:

• The actual meaning of the fragment in the cited source should not be altered. However, it is not necessary to include all details from the original passage.
• In addition, one point made in the cited fragment should not be stressed more than others. If one point needs to be stressed more, because of the direction of the literature review, then such should be mentioned.

The same page of de Moura and Botter (2017, p. 883) shows that for the same sentences a considerable number of other publications are cited, some repeatedly for the same three statements. It is unlikely that many studies have similar findings or reasoning and indicates that literature has not been well consulted. Moreover, this practice of does little justice to the authors of the works cited. This means that close reading and understanding, sometimes subtle differences, of existing publications is a prerequisite for producing high-quality literature reviews.

In addition to close reading and appropriate paraphrasing, both favourable and critical publications should be considered. An example is the literature review by Dekkers (2011, pp. 937–40) when addressing three theories for outsourcing; not only does it present how transaction cost economics, the resource-based view and the notion of core competencies can be used, but it also includes arguments from other works that have addressed deficiencies and incorrect application to domains. Thus, a high-quality literature review does not only consider supporting arguments for points made, but also examines those works that have been critiquing canonical views.

Retrieval of Sources
From published reviews it has become apparent that search strategies have changed. Quite a number of authors tend to use a range of publisher-specific databases. A case in point is Akbari (2018, p. 1552), who uses six of these publisher-specific databases; however, no rationale is presented why the databases of the publishers Hindawi, Inderscience and Sage have not been consulted. Ultimately, the purpose of a search strategy is to find as many as possible relevant publications (it is almost impossible to find all). Therefore, it is more
efficient to use generic databases, such as ABI/INFORM, Google Scholar and Scopus; in this respect, Green et al. (2006) recommend using at least two databases. Note that knowing about specific databases is helpful; the retrieval of publications through ScienceDirect is a subset of those found through Scopus, both owned by Elsevier. Sometimes, this subtle different escapes authors, such as Grubic (2014, p. 102). Also, complementary search strategies, such as snowballing, could improve finding relevant publications (see Greenhalgh and Peacock, 2005; Wohlin and Prikladnicki, 2013). This implies that the base for a solid search strategy can be found in the use of appropriate generic databases and search engines in combination with complementary search strategies.

Some authors use specific journals for retrieving relevant publications. Such is the case for Swanson et al. (2017, p. 305) identify eight journals to look into theories used for research into logistics and supply chain management; the rationale for these journals is derived from a preceding study they seek to replicate partially. Note that in case specific journals are selected, the quality of a journal is not necessarily related to the quality of a publication.

Analysis of Sources
After finding relevant sources, the subsequent analysis should be sufficiently in-depth from the perspective of the review questions. This extends to looking into origins of concepts, for example value stream mapping (e.g. Nowak et al., 2017) originates in the ASME processing mapping standard. But it also covers breaking down theories or concepts; a case in point is the decomposition of the resource-based view found in Amit and Schoemaker (1993). This analysis should lead to novel conjectures, for a manuscript to be worthy to be published.

Reporting of [Systematic] Literature Reviews
In addition to some guidelines for reporting of literature reviews, all accounts in a literature review in an academic journal should lead to conjectures. A frequently used aspect of literature reviews is the journals in which publications have been found. However, seldom does this lead to conjectures. When writing authors should ask themselves what other academics can take away from reading a literature review beyond the research the authors have in mind. The danger here is that literature reviews remain to descriptive and in this manner do not contribute to advancing research into the domain.

Also, Seuring and Gold (2012, p. 552) draw attention to the reporting, while stating that literature reviews on supply chain management often use content analysis without denoting such explicitly, they lack a detailed description of data gathering, a rationale for the pattern of analytic categories, and quality criteria such as replicability, reliability and validity. In this sense, Schlosser (2007, p. 2) stresses the importance of reporting the protocol used in the case of systematic literature reviews. Thus, reporting is of profound importance to literature reviews, even though their criteria seem to apply in the first instance to systematic literature reviews. Even when reporting the latter, all elements of a publication should lead to conjectures that build towards the finding. A common element is the reporting of journals in which relevant publications are found; often these do not lead to any conjectures or arguments, and thus, it can be questioned what should overviews contribute to such publications. In the same spirit, Lin and Evans (2012) report in a more generic form that attention should be paid to writing adequate literature reviews.
Concluding Remarks
A word of caution may be in order. Hammersley (2007, pp. 300–1) points out that though generic criteria for qualitative research, in our case the literature review, may apply, each piece of work should be assessed on its own merits. Generic criteria are found in works like Poortman and Schildkamp (2012) in addition to some publications mentioned before in this article. These criteria tend to place emphasis on transparency and rigour. Such criteria gravitate researchers to more systematic approaches, however, these have a downside, which is that they require a more specific review question (or questions). This means that literature reviews should be adequate to their purpose rather than just following a protocol or sets of guidelines.

In this respect, it should not be forgotten that literature reviews serve three purposes. The first one is that they justify particular empirical research by exploring its necessity and how it builds on extant knowledge. A second purpose is that an overview of what has been accumulated as scholarly knowledge. A final purpose is that literature reviews provide pathways for research and agenda for researchers beyond specific studies. For all three purposes, literature reviews should be compelling and inspiring, above all!

Abstract

Effectively managing working capital is a critical issue in corporate finance and recently in the operations/supply chain and finance interface area. Therefore, this paper intends to examine the patterns and productive efficiency of global firms’ working capital management (WCM) during and after global financial crisis for the period of 2008-2015. To do so, we investigate the relationship between the elements of cash conversion cycle (CCC) and return on sales (ROS). The purpose is to discover the differences, trends, and productive efficiency of WCM by different groups of firms with different profitability patterns in different industries.

Keywords: Working Capital Management, Data Envelopment Analysis, Forbes Global 2000 Time Series Data

Introduction

Effectively managing working capital is an important issue in corporate finance. It is mainly composed of a major portion of a financial part (Weston and Brigham, 1979). It could affect the firm’s profitability, risk, and value (Smith, 1980). Specifically, working capital management is an essential component of widely firms’ strategy to create shareholder value. It is a result of the time lag between the expense for the purchase of raw materials and the collection for sales of finished goods (Shin and Soenen, 1998). It contains a tradeoff between risk and profitability. Increasing the profitability tends to increase risk, and reversely, focusing on risk reduction tends to decrease potential profitability (Teruel and Solano, 2007). Cash conversion cycle is a key element in working capital management. It could reflect how much to invest in inventory and how much credit to take from suppliers (Gitman, 1974). It is a performance measure for a company to manage working capital (Richards and Laughlin, 1980).

Previous studies have analysed whether shortening the cash conversion cycle has a positive or negative effect on the firm’s profitability. Many studies found that efficiently managing cash conversion cycle tends to lead to higher profits, suggesting its importance in corporate finance management (Gentry et al., 1990; Jose et al., 1996; Shin and Soenen, 1998; Wang, 2002; Deloof, 2003; Lazaridis and Tryfonidis, 2006; Padachi, 2006; Teurel and Solano, 2007; Nobanee et al., 2011; Yazdanfar and Ohman, 2014; Linh and Mohanligam, 2018). Further, some studies have analysed the effect of the firms’ cash conversion cycle in various industries in different countries (Raheman and Nasr, 2007;
However, our study provides the different profiles of cash conversion cycle and its elements among groups of firms with different patterns of ROS during and after crisis. It is supposed to empirically investigate the relationship between cash conversion cycle and profitability ratio (ROS) for ‘Forbes Global 2000’ firms in automobile industry during (2008-2011) and after (2012-2015) global financial crisis for the period of 2008-2015. Its purpose is to provide better understanding and management tool to deal with cash conversion cycle in different time periods with different characteristics among groups.

The rest of this paper is organized as follows. In section 2, literature review is presented. In section 3, data and variables are described. In section 4, the methodology is presented. In section 5, analysis results are presented. Finally, the conclusions are discussed.

**Literature Review**

Managing working capital is an important part for firms in corporate finance management. Cash conversion cycle is a critical component in working capital management. The cash conversion cycle is typically defined as days of inventory outstanding plus days of accounts receivable outstanding minus days of accounts payable outstanding. Firms effectively can increase or decrease cash conversion cycle components such as the days of inventory outstanding (DIO), the days of accounts receivable outstanding (DRO), and the days of accounts payable outstanding (DPO) according to their policies to improve profitability.

Prior studies reveal that there are a positive significant relationship and a negative relationship between cash conversion cycle and profitability. Hawawini et al. (1986) argued that firms could increase their profitability by managing the number of days of inventory outstanding to a reasonable minimum. Jose et al. (1996) asserted that active working capital management policies increase firms’ profitability. Shin and Soenen (1998) argued that working capital management influences firms’ profitability and liquidity. Reducing working capital management leads to higher profits. Wang (2002) analysed Japanese and Taiwanese firms during 1985-1996 and showed shorting cash conversion cycle could increase operating performance. Deloof (2003) analysed that large Belgian firms from 1992 to 1996 can increase profitability by reducing the number of days of accounts receivable outstanding and by reducing the number of days of inventory outstanding. Teruel and Solano (2007) found that minimizing working capital investment would have a positive effect on the profitability of the firms. Lue et al. (2009) showed that if firm’s value increases, cash conversion cycle will be decreased. Gill et al. (2010) drew a conclusion that if cash conversion cycle is maintained at optimal level, firms could increase their profits. Oladipupu and Okafor (2013) argued that there is a positive relationship between firm’s working capital management and profitability.

However, Afza and Nazir (2007) analysed that there is a negative relationship between cash conversion cycle and profitability. Raheman and Nasr (2007) demonstrated a negative relationship between cash conversion cycle and profitability. Uyar (2009) observed there is a negative relationship between working capital management and profitability. Linh and Mohanligam (2018) indicated that cash conversion cycle has a negative relationship with profitability. Based on these studies, we could infer that firms could have industry benchmarks to manage their working capital management policies.
Data and Variables

- Data
The data used in this study was acquired from the Datastream database. It contains financial data of firms. It is panel data collected from the top 42 firms in the ‘Forbes Global 2000’ ranking in automobile industry for the period of 2008-2015. This period was divided into two sub-periods, during (2008-2011) and after (2012-2015) global financial crisis to reduce the effect from global economic conditions and better manage the patterns and productive efficiency of global firms’ working capital management in different situations (Habib et al., 2013).

- Variables
In order to investigate the patterns and productive efficiency between working capital management and profitability ratios during (2008-2011) and after (2012-2015) global financial crisis for the period of 2008-2015, the return on sales (ROS) was used as the dependent variables.

With regards to the independent variables, we used the cash conversion cycle (CCC) as a key element in working capital management. It is defined as days of inventory outstanding plus days of accounts receivable outstanding minus days of accounts payable outstanding. In this regard, the number of days of inventory outstanding (DIO) was calculated as 365 X (inventories/purchases). It can affect the average number of days of inventory. Longer storage days indicate an inventory investment for a specific level of operations. The number of days of accounts receivable outstanding (DRO) was calculated as 365 X (accounts receivable/sales). It is the average number of days that the firms can receive payments from customers. The number of accounts payable days (DPO) was calculated as 365 X (accounts payable/purchases). The firms can make their payment commitments to their suppliers (Teruel and Solano, 2007). Considering the cash conversion cycle (CCC), we used the cash conversion cycle (CCC) and each element such as days of inventory outstanding (DIO), days of accounts receivable outstanding (DRO) and accounts payable days (DPO) separately. And we used the the logarithm of sales (lnsales) as control variable.

- Descriptive Statistics
Table 1 shows descriptive statistics about the variables used for the sample. These are means and standard deviations about variables during and after global crisis. Fig. 1 depicts patterns about descriptive statistics. As shown in Table 2, we divided ROS into four groups. Based on the firms’ performance during and after global crisis, we found four patterns in the firms’ performance, i.e., some firms show high performance pattern during global crisis while other firms indicate low performance pattern after global crisis.

Methodology

For the analysis, we conduct a paired t-test method and a panel data analysis method by using panel data (Baltagi, 2001; Beasley, 1996).
In detail, first, we employ paired t-tests on ROS for the differences in means to divide the firms in different groups with different ROS trend patterns during (2008-2011) and after (2012-2015) global financial crisis (Beasley, 1996). Then, we research firms’ CCC and its elements in different groups in order to discover their ideal profiles and deviations.

Second, we apply a panel data analysis method to test the effects of CCC and its elements (DIO, DRO, DPO) on profitability ratios (ROS) (Baltagi, 2001). Estimates were acquired by the following equations:

\[
\begin{align*}
\text{ROS}_{it} &= \beta_0 + \beta_1 \text{CCC}_{it} + \beta_2 \ln\text{sales}_{it} + \eta_i + \lambda_t + \varepsilon_{it} \\
\text{ROS}_{it} &= \beta_0 + \beta_1 \text{DIO}_{it} + \beta_2 \text{DRO}_{it} + \beta_3 \text{DPO}_{it} + \beta_4 \ln\text{sales}_{it} + \eta_i + \lambda_t + \varepsilon_{it}
\end{align*}
\]

where dependent variable ROS = return on sales; independent variables CCC = cash conversion cycle, DIO = days of inventory outstanding, DRO = days of accounts receivable outstanding, DPO = days of accounts payable outstanding; control variable \(\ln\text{sales}\) = logarithm of sales, and \(\eta_i\) (unobservable heterogeneity) = measurement of each firm’s characteristic, \(\lambda_t\) = time dummy variables, \(\varepsilon_{it}\) = error terms for subscripts \(i = \text{firm}\) and \(t = \text{period}\) (Teruel and Solano, 2007).

To conduct the panel data analysis, we first test whether there is correlation between unobservable heterogeneity of each firm and independent variables of the model. If the correlation is related to fixed effect, we could take the consistent estimation through the within-group estimator. Otherwise, we could use a more efficient estimator related to random effect (Teruel and Solano, 2007). After taking Hausman test (1978), we adopted the fixed effect.

Results
Table 3 shows the results obtained after t-test results of each group about ROS performance. The results indicate there are positive correlations between group 1 and group 3,4 about DIO during global crisis. Reversely, there are negative correlations between group 1 and 3 about DRO and DPO during global crisis. There is a negative correlation between group 1 and group 4 about DPO. After global crisis, similar results are obtained about DIO, DRO, and DPO expect CCC. Regarding CCC, group 1 is positively correlated to group 4. There are positive correlations between group 2 and group 3 about DIO, and between group 2 and group 4 about CCC during global crisis. Reversely, there are negative correlations between group 2 and group 3 about DRO, and between group 2 and group 4 about DPO during global crisis. There is only a positive correlation between group 3 and group 4 about CCC during and after global crisis.

Table 3 – T-test results of each group about ROS performance
Notes: ROS = return on sales; DIO = days of inventory outstanding; DRO = days of accounts receivable outstanding; DPO = days of accounts payable outstanding; CCC = cash conversion cycle; ROS Performance Group Range 1-4 = (1 = High → High, 2 = High → Low, 3 = Low → High, 4 = Low → Low); (-) = Negative Correlation; * p < 0.1, ** p < 0.05, *** p < 0.01

Table 4 presents the results obtained after regressing the equations. During global crisis, ROS is reduced by lengthening CCC and DRO. It is increased by lengthening DPO. This result shows that firms increase their profitability by reducing CCC and DRO. Regarding control variable, it is positively correlated to log sales. After global crisis, ROS is reduced by lengthening DIO and DPO. This result provides that firms increase their profitability by reducing DIO and DPO. Maintaining days of inventory outstanding for less time improves profitability (Teurel and Solano, 2007).

Conclusions

This study provides new theoretical and practical insights into the differences, ideal profiles and productive efficiency of global firms’ WCM with different ROS patterns for automobile industry using the panel data for the period of 2008-2015. To the best of our knowledge, this study is the first attempt to investigate the crucial supply chain-finance interface issue, i.e., the relationship between WCM (CCC elements) and profitability ratio (ROS) for the period of economic crisis and recovery.

However, this study has limitations, which mean future research directions. Because the data for this study were obtained from large firms in Forbes Global 2000 rankings in automobile industry, future studies of investigating firm size effect must be considered. Furthermore, this study could be considered for firms in other industries with different product and process characteristics for the different periods and countries.

Abstract

This study examines the link between firms’ motives in adopting ISO 9001 standard and their selection criteria for certification bodies (CBs) of ISO 9001. Using the dataset drawn from 597 ISO 9001 certified firms in Australia and New Zealand, the findings show that internal motives drive firms to prefer CBs that offer strict auditing of quality system while external motives lead firms to select CBs that offer market credibility. The findings further show that CBs with strict auditing has a stronger effect on operational benefits of the certification compared to CBs that offer market credibility.

Keywords: non-financial auditing, certification, motives

Introduction

Non-financial auditing of organizational performance is becoming increasingly prevalent around the world. Non-financial auditing takes many forms and focuses on many issues, such as an organization’s quality, ethical, and sustainability practices. Like financial auditing, it focuses on comparing an organization’s performance against a reference point, such as the ISO 9001 and ISO 14001 standards for quality and environmental management systems, respectively. In any case, audits must represent a genuine attempt to cover both the positive and negative aspects of an organization’s performance (Dogui et al. 2014).

Ethical issues are inherent in all forms of auditing. Audits should be carried out by well-trained, competent auditors who are independent and free from conflicts of interest (see, for example, ISO 19011:2018). As an illustration, given the need to impartially assess an organization’s compliance with a reference point, auditors should not provide consulting on the practices they are auditing (Heras-Saizarbitoria et al. 2013). This is critical given that auditors must make numerous judgements in any audit (Power & Terziovski, 2005), even in “filter” forms of auditing (Busch, 2011).

In non-financial auditing, successful audits are often (but not always) used for certification purposes. For example, organizations may have their compliance to a management system standard, like ISO 9001 and ISO 14001, formally certified. In fact,
well over 1,000,000 ISO 9001 and over 350,000 ISO 14001 certifications have been
issued worldwide as of the end of 2017 (ISO, 2018). Organizations may seek certification
for a variety of reasons, such as customer pressure and external image (Darnall &
Edwards, 2006) or when their partners lack information or fear opportunism (King et al.
2005).

Certifications are typically issued by arms-length, third-party certification bodies, also
known as “registrars”, which employ auditors to verify compliance with a reference
point’s requirements (Pivka, 2004). Certification bodies are often expected to adhere to
standards of conduct (e.g., ISO CASCO standards) and may be registered by accreditation
bodies, such as national standards organizations, like the Joint Accreditation System of
Australia and New Zealand (JAS-ANZ). Third-party certification offers the promise of
an unbiased, independent evaluation of the organization’s conformance to the standard’s
requirements.

Ethical issues, however, have the potential to compromise the auditing and
certification process. For example, organizations typically have discretion in selecting a
certification body, and frequently can choose among many options (Dogui et al. 2014).
A further complication is that audits are usually “contracted and paid for by the company
that wishes to become certified” (Heras-Saizarbitoria & Borial, 2013, p. 59). This can call
into question the “independence and impartiality of the certification process” (Dogui et

Ethical issues in non-financial auditing and certification processes are in need of
further research (Heras-Saizarbitoria & Borial, 2013). Although third-party certification
may provide an organization with increased credibility and legitimacy, there is no
guarantee of honesty in the certification process (Heras-Saizarbitoria & Borial, 2013;
King et al. 2005). The purpose of this paper is to investigate the role of certification body
selection in the quality of third-party audits. We investigate whether organizations select
certification bodies on the basis of audit strictness or market credibility. We also study
the operational and market benefits that arise from the audit. Two key research questions
guide our study:

• RQ1: How do organizational motives impact the selection of certification bodies?
• RQ2: How do certification bodies and organizational motives impact the benefits
  of certification?

To answer the research questions, we surveyed 597 companies in Australia and New
Zealand registered to ISO 9001. We focus on ISO 9001 since it is the world’s most
popular non-financial management standard. Building on an earlier study (Castka et al.
2015), we find that organizations’ motives define their preference of certification bodies’
characteristics (i.e., whether they offer strict audits or market credibility), and that
organizations’ motives are also most important in driving the real benefits achieved.

The paper makes several contributions. First, it adds to the limited empirical research
on how firms choose certification bodies (e.g., Castka et al. 2015; Poksinska et al. 2006).
None of the earlier literature has studied this issue from an ethical perspective. Second, it
is the first paper to study how organizational motives influence the selection of
certification bodies, and how those collectively influence the audit benefits. Third, we
build on legitimacy theory to articulate the ethical implications of organizations’ auditing
preferences. We explore the implications of the possibility of organizations to obtain
benefits, even if this requires them to unethically avoid strict audits.

Theoretical Background
ISO 9001 was introduced in 1987 and has been updated four times, most recently in 2015.
The standard includes an extensive set of requirements intended to help an organization
improve its product quality, but it does not specify required levels of performance or methods to meet the requirements. Certification mechanisms for ISO 9001 have also evolved over time, and have become “increasingly structured, professionalized, and codified” (Borial & Gendron, 2011, p. 335). Moreover, as the world’s most popular non-financial management standard, ISO 9001 has helped shape the development of other non-financial management systems and their certification mechanisms (Boiral & Gendron, 2011).

Organizations have considerable discretion in terms of how they meet ISO 9001’s requirements and research has shown there is considerable heterogeneity in its implementation (e.g., Heras-Saizarbitoria & Boiral, 2015; Storz, 2007; Walgenbach, 2001). Organizations can implement the standard differently, even when responding to similar pressures (Heras-Saizarbitoria & Boiral, 2015). The variety of methods organizations can use to implement ISO 9001 underlines the importance of auditors’ judgement in certification audits. Auditor independence is particularly critical, since “the certification process is most often depicted as a rational, neutral, and unequivocal process” (Boiral, 2012, p. 633).

Certification audits are often regarded as “trust-providing” processes that provide social legitimacy through impartial verification (Boiral, 2012, p. 634). Trust in certification audits, however, can be undermined by the “customer-supplier” relationship between the organizations being audited and the contracted certifying bodies (Boiral & Gendron, 2011, p. 338). Conflicts of interest, for example, can lead to a superficial audit (Boiral & Gendron, 2011). Research has shown that different auditors and certification bodies can have vastly different expectations (Poksinska et al. 2006). To avoid issuing unworthy certifications, auditors (and, more broadly, certification bodies) must be particularly alert to “decoupling” between organizations’ stated and real practices (Meyer & Rowen, 1977), a phenomenon that has been studied extensively in a management standards context (e.g., Boiral, 2007).

Unfortunately, there is evidence that organizations frequently adopt ISO standards symbolically (Boiral, 2003; Christmann & Taylor, 2006; Heras-Saizarbitoria & Boiral, 2015). This can perpetuate “rational myths”, where practices are perceived as legitimate even though they have only ceremonially been implemented (Boiral, 2007 and 2012; Heras-Saizarbitoria & Boiral, 2015). Such differences between rhetoric and reality have long been recognized (e.g., Zbaracki, 1998). When organizations that have not internalized (Kostova & Roth, 2002) a standard’s requirements receive certification, a “performance-portrayal” gap (Adams, 2002) can emerge (i.e., management systems lacking rigor are formally recognized). This can further encourage seeing certification as an end in itself, analogous to degree-purchasing syndrome in education, whereby organizations “acquire ISO certification as a sort of ‘organizational degree’ after passing a quite predictable exam” (Boiral, 2012, p. 633).

Legitimacy is, thus, one of the key drivers for organizations seeking to obtain ISO 9001 certification. As Boiral and Gendron (2001, p. 338) explain, ISO 9001 certification is “driven by a quest for institutional legitimacy through the adoption of internationally recognized practices that aim to demonstrate the organization’s accountability with respect to quality.” Legitimacy has been defined by many authors, but here we adopt Suchman’s (1995, p. 574) widely-cited definition: “a generalized perception or assumption that the actions of an entity are desirable, proper, or appropriate within some socially constructed system of norms, values, beliefs, and definitions”.

Research shows that “ceremonial integrators” of ISO 9001 (i.e., organizations superficially adopting the standard) are especially motivated by external legitimacy (Boiral, 2003; Heras-Saizarbitoria & Boiral, 2015). A wide range of benefits have been
associated with increased legitimacy from certification, such as helping an organization improve its image, legitimize its activities, and satisfy stakeholders (Boiral, 2007, p. 129). However, as Boiral (2007) implies, when requirements have only ceremonially been implemented, organizations may leave themselves open to charges of “organizational hypocrisy” (Brunsson, 1989). These concerns could be particularly magnified due to certification bodies’ potential conflicts of interest arising from, for example, the competition amongst themselves and their position as a certification supplier to an audit customer (Borial & Gendron, 2011).

All of these issues cast “doubt on the imagery of impartiality, rigor, and accountability projected by organizations through discourses of certification” (Boiral & Gendron, 2011, p. 331). A third-party audit, therefore, does not necessarily prevent the legitimation of poor performance. While strict audits, defined below, can prevent legitimizing poor performance, weak audits can be used for that very purpose. Certifying unworthy organizations goes against the interests of stakeholders, such as customers and the general public. Ethical certification bodies, more focused on strict auditing than market credibility, are critical to preventing this problem. There is a need to study how organizational motives impact the selection of certification bodies and how, in turn, certification bodies and those motives impact the operational and market benefits earned by standard certification.

Hypothesis Development
The purpose of certification is to differentiate between organizations that have met a standard’s requirements and those that have not. Ethical issues, such as conflicts of interest, have the potential to blur that distinction. When organizations have a genuine desire for a strict audit, i.e., one that rigidly adheres to and fairly assesses compliance with a reference point’s requirements, this purpose may still be achieved. However, when organizations are more interested in obtaining the market benefits of certification, and are willing to pursue those at any cost (including certifying undeserving practices), they could unethically use certification as a means to legitimate their behaviour. We term the desire for a strict audit vs. one focused on market benefits as an organization’s auditing preference.

Organizational motives for pursuing ISO 9001 certification have been widely studied. They include improving products, enhancing productivity, gaining market access, growing market share, improving supply chain management, improving profitability, reducing information asymmetries, responding to customer pressure, or improving external image, among others (Boiral & Roy, 2007; Castka et al. 2015; Castka & Balzarova, 2010; Corbett, 2006; Darnall & Edwards, 2006; King et al. 2005). In this paper, we categorize organizational motives for pursuing certification as internal and external motives. We focus specifically on building a foundation for systematic business management and establishing a springboard for continuous improvement as internal motives. Our external motives of focus are meeting customer and market requirements and enhancing the organization’s image and reputation.

The motives listed above demonstrate that organizations seeking certification to a standard, like ISO 9001, often pursue certification as a mechanism to legitimize their behaviour, and, ultimately, help shape social perceptions. Organizations genuinely meeting ISO 9001’s requirements have earned the legitimacy conferred by certification. These organizations may select certification bodies on the basis of audit strictness. Organizations, however, may be interested in the benefits of being recognized as certified to a standard’s requirements even in cases where they do not actually meet those
requirements. These organizations may select certification bodies on the basis of the market credibility they offer.

Organizational motives for selecting certification bodies have not been widely studied, though the limited research available supports the assumptions above. Castka et al. (2015) found that certifier selection is influenced by an organization’s auditing preferences and that organizations interested in genuine improvement tend to choose reputable certification bodies. We build on Castka et al.’s (2015) study to investigate the effect of an organization’s audit motives on its auditing preferences. Based on the above, our first two hypotheses directly address RQ1 and lay the foundation for addressing RQ2.

- Hypotheses 1 (H1): Internal motives have a stronger association with CBs offering strict auditing than with CBs offering market credibility
- Hypothesis 2 (H2): External motives have a stronger association with CBs offering market credibility than with CBs offering strict auditing

The benefits of ISO 9001 certification are closely tied to the motivations listed above. In this paper, we consider that operational benefits (i.e. quality of products/services and efficiency of the processes) as reflecting the true intent of the ISO 9001 standard. Whether these benefits are realized in practice, however, depends on how the standard is actually implemented, to respond to many studies which have questioned the effectiveness of ISO 9001 and its real impact (see, for example, Boiral & Roy, 2007). In this regard, CBs will play an important role to ensure that firms have demonstrated their serious commitment in implementing the requirements of ISO 9001 standard by focusing on substantive (e.g., actual practices) rather than ceremonial (e.g., overreliance on documentation) aspects of the audit process (Boiral & Gendron, 2011).

We argue that organizations that have genuinely implemented the standard’s requirements and have sought a strict audit, are more likely to obtain stronger operational benefits than organizations that have not. They are also likely to obtain market benefits. Organizations that seek certification purely for market credibility purposes, however, are more likely to try to legitimate poor practices. Although they are less likely to obtain operational benefits than organizations that have substantively implemented the standard, they may still be able to obtain the market benefits conveyed by the third-party certification and use it as a “rubberstamp”. The certification which is focused on ceremonial aspect of ISO 9001 results in a performance-portrayal gap that helps explain the unethical distortions that arise when companies are able to legitimate unworthy performance. Based on the above, our next hypothesis focus on the effect of CBs preferences on the benefits of ISO 9001 adoption, which aims to address RQ2.

- Hypothesis 3 (H3): CBs offering strict auditing have a stronger association with operational benefits than do CBs offering market credibility

Method

Sampling and procedures
The participants were selected for participation in this study from a JAS-ANZ database that lists all Australian and New Zealand companies that are certified to ISO 9001. From a total of over 10,000 companies listed in this database, 4,000 Australian and 1,000 New Zealand companies were randomly selected and received our survey. Targeted respondents to the questionnaire were managers within each organization who had knowledge and responsibility for the implementation and maintenance of the company’s quality management system. In total, 597 usable responses were received from Australian firms and New Zealand firms.
**Measures**
The content of the scales for internal motives, external motives, and operational benefits are derived from the study by Nair and Prajogo (2009). The two characteristics of CBs are measured by a single item that reflects firms’ reason for selecting the CB, namely “Our CBs offering strict quality auditing” and “CBs offering market credibility”, taken from Castka (2013).

**Results**

**Scale validity and reliability**
All five scales were subjected to validity and reliability test. The results show acceptable fit as indicated by several key fit indices (RMSEA = 0.056, NFI = 0.984, CFI = 0.989, and GFI = 0.990). However, the output also suggested the covariance between the errors of two items (i.e. “To build a foundation for systematic business management” and “To meet customer and market requirements”). We consider that the covariance ($\psi = -0.07$ at $p < 0.01$) deemed plausible as it shows the contrast (negative correlation) between internal motives and external motives. Adding the covariance has improved the measurement model significantly as indicated by the significant drop of the chi-square value from 17.51 down to 8.90. All other fit indices are also improved (RMSEA = 0.036, NFI = 0.992, CFI = 0.996, and GFI = 0.995. The complete results of the CFA are presented in Table 1 below.

*Pearson $r$ correlation (significant at $p < 0.01$) is used instead of Cronbach’s alpha for measuring reliability since the scale only has two items. Pearson $r$ values above 0.2 suggests good reliability

**Structural relationship**
The hypotheses are tested simultaneously using Structural Equation Modelling (SEM) technique using latent variables. However, since constructs “CBs offering strict quality auditing” and “CBs offering market credibility” are measured by one observed variable, we need to convert them into latent variables by setting the loading path of the observed variable to the latent variable to be 1 and the error variance of the observed variable to be 0. The similar processes are also applied for the two control variables (firms’ size and the year of certification) in the research model. In addition, we also believe that selecting auditor is not the only essential strategy that firms take in realizing their motives in adopting ISO 9001 and achieving the outcomes of the adoption. Studies have shown that the implementation of the ISO 9001 standard, such as training employees and developing and maintaining procedures), for example, is also driven by motives and has significant effect on the outcomes (firms’ performance). In other words, CBs selection does not fully mediate the relationship between motives and outcomes of ISO 9001 adoption, hence, we need to set the direct path between the two motives to operational performance.
The research model presented in Figure 1 shows a good fit as reflected by the key fit indices ($\chi^2 = 27.84$ with degree of freedom ($df$) = 21, RMSEA = 0.023, NFI = 0.984, CFI = 0.996, and GFI = 0.991). Looking at the path coefficients, there are indications for supporting our comparative hypotheses. Internal motives show relatively stronger effects on CBs offering strict auditing compared to CBs offering market credibility ($\gamma = 0.23$ at $p < 0.01$ versus $\gamma = 0.11$ at $p < 0.05$ respectively), supporting H1. Similarly, external motives show relatively stronger effects on CBs offering market credibility compared to CBs offering strict auditing ($\gamma = 0.40$ at $p < 0.01$ versus $\gamma = 0.23$ at $p < 0.05$ respectively), supporting H2. Finally, CBs offering strict auditing shows a relatively strong effect on operational benefits than do CBs offering market credibility ($\gamma = 0.23$ at $p < 0.01$ versus $\gamma = 0.05$ at $p > 0.05$ respectively); hence, H3 is supported.

![Figure 1 Research model](image)

* $p < 0.05$ ** $p < 0.01$

However, in order to test the three comparative hypotheses, we need to test if the two paths that we compare are significantly different by creating a competing model where the two paths are set to be equal. In testing H1, we created a competing model by setting the two paths from internal motives to CBs offering strict auditing and to CBs offering market credibility to be equal. This results in an increase of $\chi^2$ to be 34.72 at $df = 22$, hence, producing $\Delta \chi^2$ of 6.88 with $df = 1$ to the original model. The value of $\Delta \chi^2$ is greater than 6.63 to support that the two models are significantly different at $p < 0.01$. Therefore, the result suggests that setting the two paths to be equal decreases the model’s fit; hence, we can conclude that the two paths are different and since the path from internal motives to CBs offering strict auditing is stronger than that to CBs offering market credibility, we can conclude that H1 is supported. Similar procedure is applied for testing the other two hypotheses. In testing H2, the competing model which sets the path from external motives to CBs offering market credibility to be equal to the one to CBs offering strict auditing produces $\chi^2 = 38.31$ at $df = 22$, hence, resulting in $\Delta \chi^2$ of 10.47 with $df = 1$ to the original model. The value of $\Delta \chi^2$ is greater than 6.63 to support that the two models are different at $p < 0.01$; hence, supporting H2. In testing H3, the competing model which sets the path between CBs offering strict auditing and operational benefits and the path between CBs offering market credibility and operational benefits to be equal produces $\chi^2 = 31.57$ at $df = 22$, hence, resulting in $\Delta \chi^2$ of 3.73 with $df = 1$ to the original model. The value of $\Delta \chi^2$ is very close to 3.84 to support that the two models are different at $p < 0.05$ (or at least at $p < 0.1$); hence, supporting H3. Indeed, the effect of CBs offering market credibility to
operational benefits is non-significant (as shown earlier), providing further support for H3.

Finally, the model shows that internal motives also show a significant path on operational benefits ($\gamma = 0.40$ at $p < 0.01$) while external motives do not ($\gamma = 0.05$ at $p > 0.05$). This result is compelling in two ways. First, it shows that firms will have other strategies or mechanisms to realise their internal motives in adopting ISO 9001 standard and achieve the intended outcomes (i.e. operational benefits) over and above selecting appropriate CBs. At the same time, the result also shows that external motives have no direct effect on operational benefits, and even their indirect effect on operational benefits is fully mediated by CBs with strict auditing. This finding, therefore, provides evidence on the importance of having the right motives in adopting the ISO 9001 standard.

**Discussion and Conclusion**

The findings have shown the implications of two contrasting motives for selecting CBs in adopting the ISO 9001 standard. If a firm’s internal motives reflect a desire to build a solid quality management system in its business operations, this will likely lead it to show a serious commitment to implementing the standard, which also impacts how they choose CBs. Our findings clearly show that, in selecting the CB, firms driven primarily by internal motives will focus more on a CB that shows uncompromising quality in the auditing process (i.e., a strict audit) instead of offering primarily market benefits (as per H1). This is because these firms are focused on the substantive aspect of ISO 9001 (i.e., a solid quality management system) rather than the ceremonial aspect (i.e., certification). While they still seek ISO 9001 certification, firms driven by internal motives consider it as a secondary outcome of adopting the standard. As demonstrated by our findings, their primary focus is on high quality products and an efficient process.

External motives, on the other hand, reflect institutional pressures to attain ISO 9001 certification. Firms driven by these motives are more focused on seeking the legitimacy conferred by certification (i.e., a ceremonial aspect) rather than building a quality system (i.e., a substantive aspect) as prescribed by the standard. In seeking legitimacy, external motives would lead firms to mainly focus on obtaining certification from a CB that is well recognized in the market. This motive leads firms to base their selection on CBs with high market credibility rather than those with high audit strictness (as per H2). In other words, institutionally-driven motives lead firms to seek an enhanced, institutionally-driven image. However, as the findings show, increased market credibility does not necessarily reflect the true value intended by ISO 9001 standard. Our results suggest that it does not have a positive effect on operational benefits, hence, delivering significantly lower value for ISO 9001 adopters (as per H3).

From an ethical perspective, we can draw several insights from the findings. First, our findings show that CBs offering market credibility have a significantly weaker effect on operational benefits than CBs offering strict audits; indeed, they have no significant effect. This finding draws a sharp distinction between the substantive and ceremonial aspects of obtaining certification. The failure (non-significant effect) of CBs offering high market credibility, but low audit strictness, in delivering operational benefits for their clients indicates the potential for an ethical problem where firms expect to receive operational benefits arising from certification, but do not. Engaging the wrong CBs, which deliver low (or no) real operational benefits from ISO 9001 adoption (other than the certification) could explain the growing disillusion many companies are experiencing in standards adoption (e.g., Castka and Corbett, 2015; Lal (2004)).

Second, in conjunction with the first ethical issue, the failure of CBs to adequately distinguish between companies that have substantively and symbolically implemented
the standard is creating market distortions that can lead to customer manipulation. ISO 9001 is a widely-recognized management system standard and its certification is intended to offer customers assurance of the certified firm’s ability to deliver products meeting specified requirements. Being certified by recognized CBs could increase the level of customer confidence, yet, as the findings show, even certified companies may not be capable of delivering on customer expectations. This problem is paramount given that most customers cannot themselves check the quality of their suppliers’ processes, and, therefore, must rely on the certification for gaining this assurance. The certification of undeserving ceremonial integrators of ISO 9001 can also adversely impact the reputation of the standard and, more broadly, non-financial auditing, resulting in a cynical view on standards adoption (Boiral, 2003).

Third, formally recognizing firms that have only symbolically implemented ISO 9001 can have a number of cost implications. Firms are responsible for covering the costs of audits provided by certification bodies, which can often be substantial, particularly when the costs of surveillance and renewal are also considered. Customers expecting products meeting their requirements due to their production in a certified system, may also incur costs associated with, for example, unanticipated low product quality or paying a premium for products produced under certified conditions. Although we do not specifically address the issue of costing in this study, the high cost for engaging CBs or paying for products produced by certified firms may not deliver value commensurate to the cost.

Fourth, the findings shed light on the perils of certification bodies finding themselves in a customer-supplier relationship with the organizations they are contracted to audit (Boiral and Gendron, 2011). The increasing commercialism and competition amongst the certification bodies themselves (Boiral and Gendron, 2011), combined with limited enforcement power of national standards organizations (i.e., the accreditors of certification bodies) is fostering an expectation that organizations (i.e., customers) will get what they want and pay for (i.e., a “lenient” audit result), rather than what they deserve (i.e., a fair audit). The findings show that, if they are motivated to do so, organizations will be able to obtain certification even if they are not genuinely committed to the standard. These issues create ethical dilemmas for organizations, auditors, and certification bodies. For example, certification bodies and their auditors face dilemmas arising from their conflicts of interest, such as their need for impartiality from, while being financially dependent on, their customers.

In conclusion, our study has demonstrated the ethical issues pertaining to the auditing and certification process of the ISO 9001 standard. This study is one of the first to explicitly adopt an ethical perspective on the role of certification bodies in implementing ISO 9001, and, more generally, in the auditing field. One recommendation we propose is the need for better regulating CBs, through strengthened enforcement powers of national standards organizations, to ensure that they operate according to the basic principles intended by ISO 9001 standard. Such regulation would reduce unethical behaviours not only from the CBs who do not perform strict audits, but also from clients who seek to legitimate poor performance, thus capturing the benefits of legitimation without actually doing the things for which they have been certified.

Rajendra Mishra School of Engineering Entrepreneurship, Indian Institute of Technology Kharagpur, India - 721302

Abstract

Smart product development (SPD) in industry 4.0 facilitates decision making during different activities involved in development process. Contextual evidence shows such activities are influenced by several factors; however there remains little understanding on factors influencing SPD from industry 4.0 in Indian context. Present study aims to identify and develop perception based prediction model to investigate critical factors influencing SPD. Two dimensions extracted viz. “technological” and “strategic” factors have significant positive impact while out of five identified critical factors three have significant positive impact i.e., technology & innovation, system integration and collaborative engineering. Thus, increasing quality of industry 4.0 can be accomplished with proper integration of technologies.

Keywords: Critical factors, India, Industry 4.0, Smart product development

Introduction

With the advancement of digital technologies and a paradigm shift to industry 4.0 manufacturing industries have been found to be in major transformation towards adopting smart manufacturing (Feeney et al., 2015). This new industrial trend affects organizational structure and customer’s demand (Gilchrist, 2016) which resulted into development of complex and smart products with new capabilities thus influence product life cycle that is somewhat different from conventional product development approach (Nunes et al., 2017; Ahmed et al., 2019). Industry 4.0 is an integration of “intelligent systems, machines, production and processes to form a well-defined network” (Kagermann et al., 2013, cited in Ahmed et al., 2019). It is a concept that involves combined components of “cyber physical systems (CPS)”, “internet of things
(IoT)” with cloud based models as disruptive technologies (Wang et al., 2015; Dalenogarea et al., 2018). It produces new types of products with intelligent systems embed in it. Despite the recognition of the term “smart” as extensively used by many organizations and researchers, still today there is no consensus of consistent definition. The concept of “smart product” is a network based integrated approach that spans entire manufacturing process and control production stages/processes autonomously (Nunes et al., 2017). It is characterized by its computation and data-storage facilities and its way of interaction with other objects. From developing economy like India manufacturing industry resembles high priority sector in terms of wealth creation and employment generation. However, such development initiative is still in its concept phase and has got immense potential to bring positive effects in terms of cost, quality, productivity, time, flexibility and innovation. Traditional product development approach consisting of multiple processes and sub-processes that interferes decision making information and knowledge capture (Ahmed et al., 2019) and hence real time decisions cannot be taken (Wasim et al., 2013). This becomes an imperative for development of frameworks for smart products so as to offer unprecedented customer insights. In-spite of several advantages in combining industry 4.0 and SPD, majority of the Indian industries are in state of dilemma with respect to its adoption and implementation. Contextual evidence indicates that factors that influence traditional product development approach may not be same as in case of smart product development. Thus the purpose of this paper is to identify the critical factor dimensions that affect smart product development from Indian industry 4.0 perspective. Accordingly the following objectives have been considered.

**Objectives:** (i) To identify and predict the influence of critical attributes or indicators on SPD; (ii) To identify critical factor dimensions and its influence on SPD.

**Hypotheses Development**

*Technology and Innovation*

With high-technology development influenced by innovation facilitates product design and development process. Such innovation led technological development engenders substantial changes in existing market that leads to successful product development. Quality of the product can be improved with technology intervention as organizations are moving towards digitalization in context of industry 4.0. Development process of smart product entails diffusion of advanced technologies and equipment, advanced production procedures with upgraded software and databases. Thus it is expected that ‘technology and innovation’ would increase the process flow by focusing on process innovation. Accordingly the following hypothesis is proposed.

H1: Technology innovation has positive influence on smart product development

*Collaborative Engineering*

Collaboration, in terms of human interface perspective, aids towards execution of series of activities which provides channel for team. Collaborative product development from
engineering perspective is a technology oriented process that is used to design innovative and improved products by exploring new markets so as to gain competitive advantage (Büyüközkan and Arsenyan, 2012). From the literature it is evident that collaborative process is followed in many industries those are involved in complex product and service development including research and development (Feller et al., 2005). Collaborative engineering also focuses in handling problems in relation to partner selection and evaluation which is critical for product development success. Thus following hypothesis is proposed.

H2: Collaborative Engineering has positive influence on smart product development

System Integration

Pertaining to SPD from Industry 4.0 perspective, SI refers to cyber physical systems that interconnect physical systems and communication infrastructure (Baheti et al., 2011). Integration of cyber technologies make products internet enabled that generates lots of data and communicates with other interconnected products. These facilitate product development process which can be achieved in cost effective and effectual manner. With system integration approach flexible operations could be performed by adjusting combination of standardized modules that speed up the product development process and reduces time to market. Thus following hypothesis is proposed.

H3: System integration has positive influence on smart product development

Sustainability

Sustainability is considered to be a critical attribute that strategically addresses the risk management in product development. With reference to environmental perspective issues pertaining to sustainability related to smart products focuses on reducing wastes, resources and energy thus moving towards green products. Reducing series of activities pertaining to traditional product development approach would eventually make the process efficient and eliminate any special causes of defects which ultimately lead to product development success. Moreover, economic sustainability facilitates agility and smooth flow in smart product development with objective to maximize profit and minimize costs. Thus the following hypothesis has been proposed.

H4: Sustainability issues have positive influence on smart product development.

Lean Operating System

Lean implementation is initiated by cyber physical system (CPS) which results in elimination of wastes by maximizing productivity. Such implementation produces products at low production costs, with good quality, better accessibility to market and customer satisfaction. Lean aspects of product development include knowledge based engineering focusing on smart technology, mistake proofing, and continuous improvement as core enablers for process development (Khan et al., 2013). Knowledge based platform proposed in work of Ahmed et al. (2019) demonstrates the influence of
advanced lean technology in product development process using knowledge-based engineering. Thus the following hypothesis is proposed.

**H5:** Lean Operating System issues have positive influence on smart product development.

**Methodology**

In order to address the research objective the present study adopts qualitative and quantitative approaches. A comprehensive search on related literature has been conducted to identify critical attributes of SPD in context of industry 4.0. To carry out qualitative based approach a semi-structured questionnaire was prepared in understanding the contextual attributes and accordingly an in-depth interview is carried out from ten manufacturing organizations where respondents were from top management and managers who have got experiences of working in domain of product development. Criteria for selecting respondents were such that they should have atleast served for minimum of eight to ten years as senior manager category with respect to design, R&D, marketing aspects of product development. Organizations involved in manufacturing products that includes consumer based household appliances and intelligent medical devices are considered in this study. Overall five critical attributes have been finalized to be taken into consideration from industry 4.0 perspectives. With identification of critical attributes of SPD attributes a structured questionnaire is developed and respondents were asked to give their opinion for each attributes on 5 point Likert scale ranging from “5= strongly agree” to “1= strongly disagree”. A structured questionnaire was sent to around 250 organizations, out of which 200 organizations responded. Out of 200 questionnaires received 35 found to be with missing data thus total 165 questionnaires were taken into consideration for further data analysis. Overall 165 respondents’ opinion is finally captured for data analysis. SPD is taken as dependent variable in terms of product development success considering operational performance measures. To establish link between predictor and dependent variables proposition have been drawn considering literature and contextual understanding (Büyüközkan and Arsenyan, 2012; Hermann et al., 2014; Kiel et al., 2016; Jianfan et al., 2017; Mrugalska and Wyrwicka, 2017; Kamble et al., 2018). Thereafter, a step-wise multiple linear regression modelling is performed to study the influence of all the five models on SPD. Secondly, factor analysis with PCA (principal component analysis) is done on five attributes to extract and identify the critical dimensions. Third, the extracted critical dimension is further subjected to regression analysis to predict and understand the relationships between extracted factor dimensions and dependent variable (SPD success). In this study SPD is taken as dependent variable which is measured by both operational and quality performance.

**Data Analysis and Results**

This research is exploratory in nature. From quantitative perspective firstly a step wise multiple linear regression modelling is executed which shows all five models are statistically significant with positive and significant impact on SPD. The data being
captured were further subjected for corroboration to see whether it could be analyzed through factor analysis or not. Accordingly, we performed the following analysis: (i) Correlation Analysis: Correlations were high among the practices; (ii) stepwise regression model of critical attributes on SPD (iii) Bartlett’s Test of Sphericity: Found to be significant (p < 0.05), this shows the acceptability of data; (iv) Kaiser Meyer Olkin Test (KMO): KMO test has been found to be 0.752, which is well above cut-off range; (iv) cronbach alpha: overall is 0.791, F1 is 0.823 and F2 is 0.696. Therefore based on analysis it can be concluded it is appropriate to conduct factor analysis (Meyers, 2006; Pallant, 2007). Before conducting factor analysis we performed univariate and multivariate statistics of the variables and discovered no apparent outliers (Jun et al., 2006). To further confirm the existence of normality we conducted two tests i.e. Kolmogorov-Smirnov and Shapiro- Wilks tests, which shows p value to be greater than 0.05 and therefore revealed normal distribution.

**Note:** Dependent Variable is Smart Product Development (SPD); TI: Technology and Innovation; SI: System Integration; CE: Collaborative Engineering; LOS: Lean Operating System; SUST: Sustainability
Factor analysis is performed on five critical indicators as identified from review of literature and contextual understanding based on qualitative study. We conducted factor analysis on explanatory variables/indicators with objective to determine minimum number of factors that accounts for maximum variance in data. The factors were extracted using principal component analysis (PCA with varimax rotation). The objective of deploying PCA is to reduce the number of variables (Jolliffe, 2002). PCA is used to “extract maximum variance from the data set with each component thus reducing large number of variables into smaller number of components” (Tabachnick and Fidell, 2007), which facilitate easier interpretations. Table 3 exhibits rotated component matrix which shows all the five variables having factor loading of more than 0.5 and further could be reconfigured into two factor dimensions as being extracted. Factor dimensions extracted are labeled as “Technological” (F1) and “Strategic” (F2).

The overall reliability analysis shows Cronbach’s alpha to be 0.791 which validates the reliability of the study. Further reliability analyses show Cronbach’s alpha values for factor dimensions F1 and F2 to be 0.823 and 0.696 respectively, which validates the reliability of the factors being extracted. Regression analysis is performed on two extracted factors. The model explains the variance ranging between 46.8% to 53.5% i.e. the predictors explains the variance in the dependent variable well which is more than the standard 40%. Durbin- Watson index suggests that there is no problem of autocorrelation in data. F-value and VIF indicates that overall model has no multicollinearity problem.
Overall, analysis (Figure 1) indicates the importance of technological factors which can be regarded as critical dimension for SPD. It is expected that from industry 4.0 perspective, IoT could have capability to offer transformational solutions for solving the complex digital issues in complex digital environment. In our opinion smart India in future would add value to realisation of industry 4.0 by deploying cloud manufacturing / manufacturing-as –a- service (Maas) which is gaining importance in manufacturing industry. Cyber-physical systems resemble a significant technological enabler for smart product development.

Findings and Discussions
The stepwise regression analysis reveals that attributes like technology and innovation (TI), system integration (SI) and collaborative engineering (CE) have significant positive impact on SPD whereas attributes like lean systems (LS) and sustainability (SUS) have insignificant impact on SPD. The impact analysis of technological innovation indicates that Indian industries are moving towards digital manufacturing where product development process will be executed through organised application of scientific knowledge and is consistent with Hecker (2005). With intervention of advanced technologies it is also likely that developmental process is driven by innovations that add value to the products which facilitates market demand. Here, SI resembles critical significance of cyber physical systems (CPS) where organizations would be able to generate large chunks of production data for real time analysis and decision making. Perception of respondent’s towards SI also confirms the rapid move of manufacturing organizations to adopt IoT (internet of things) based approach where objects/ entities are virtually interconnected with lots of data being generated. CE approach also shows the significance of concurrent engineering management on the developmental process of SPD. As SPD from industry 4.0 perspectives is in its stage of infancy thus it would take some time to apply lean systems management and to develop a sustainable framework. Although TI, SI and CE models have been found to be statistically significant however impact of TI, SI found to be strong and CE to be moderate. This shows the lack of prominence in teamwork and human resource
Exploratory factor analysis extracted two factor dimensions which are referred to as constructs namely “technological” and “strategic” factors respectively. Based on analysis performed, automatic linear modelling shows that both technological and strategic factors have significant impact on SPD which is interesting and thus exhibits paradox. The paradox itself gives an impression that strategic factor alone could not significantly impact SPD when acting alone but can significantly influence when combined effect of each technological attributes (TI, SI and CE) is deployed which shows complementarity effect with other resources. The results indicate that Indian industries with respect to Industry 4.0 anticipate better digital adoption with reduced operational costs and productivity improvement. The significant influence of strategic factor indicates the importance of triple bottom line (3BL) with lean initiatives as critical strategic components towards successful SPD initiatives. The perceptual measures from technological perspective expected to exhibit digital automation with integrated sensor systems as one of the most implemented technologies. The results obtained based on analysis gives an overall impression that increasing quality of industry 4.0 can be accomplished with proper integration of technologies and strategy. The integrated application of technological and strategic factor dimensions indicates that when products embed with advanced technology it increase intelligence and play strategic role. From lean initiatives the results indicate the possible dominance of design engineers to hide unwanted and irrelevant features and reduce environmental impact of product. Findings exhibit an overall impression that strategic/ intelligent product information is likely to be utilized as part of user-centered design process, where industrial designers can take advantage of smart product’s life cycle management. Overall the perception based findings show that advances in semantic and sensing technology can change approach of user interaction with products which eventually leads to product development success.

**Contribution of the Study**

In this study attempt has been made to analyze the perception of Indian organizations which are involved in product development in order to measure the impact of factor dimensions on SPD in terms of expected implementation benefits. Since the concept of smart product development from industry 4.0 in Indian context is in its stage of infancy and the scarcity of literature available in the said context clearly shows the prominence of the present study and its contribution. Results demonstrate the emergence of two constructs (technological and strategic) which are positively associated to expected benefits in terms of SPD success. The main contribution of this paper is identification of emerging constructs (herein referred to as factor dimensions) of SPD and how these factor dimensions are seen in emerging economy context like India, since most of the studies have been done from developed nations perspective. In this regard the present study showed how technological and strategic factor dimensions are associated with projected benefits of SPD. The designated approach using quantitative model for industries 4.0 gives industries the opportunity to learn regarding solutions from techno-strategic aspect which may be deemed to be a novel contribution from Indian context since Industry 4.0 is still in concept development phase.
Conclusions
In this paper the current industrial development on smart products from industry 4.0 in Indian context has been represented. The attributes and factor dimensions influencing SPD gives a preliminary overview regarding developmental process based approach for smart products. SPD from industry 4.0 perspective in Indian context being relatively new thus there is always a possibility of high degree of uncertainty and technological know-how for real-time implementation. Hence, present study would be beneficial for its application based findings which could be taken up by the industries as partial guidelines to undertake implementation procedures from both technology and strategic perspectives.

Practical Implications
Results derived from this study can be beneficial to operations manager and industry policy makers to execute decisions at all levels from strategic, tactical and operational aspects. From operational perspective the results exhibit which attributes are critical for successful implementation of SPD. Considering the present industrial scenario the results would provide partial guidelines to the industries who wish to adopt the strategy of industry 4.0 and think which attributes should be considered. Accordingly based on competitive priorities industries can develop and design their implementation strategies. On other hand industrial policy makers can use the findings of this study to initiate policy level decisions as to what technology and strategic dimensions need to be considered during developmental phases of smart products in order to achieve competitive advantage. For example technological attributes like TI, SI and CE could be strong trending patterns followed by strategic attributes like lean systems and sustainability. Results and findings derived from this study can be beneficial to operations manager and decision makers to design their implementation strategies.

Limitations and Future Scope
In this study five critical attributes of SPD have been considered and there is a scope to explore more number of attributes from industry 4.0 perspective. From statistical perspective the study has some limitations since we considered perceptual measures based on respondent’s opinion from industry 4.0 context, thus there may be possibility of respondent’s bias. Secondly, there is a scope to increase number of respondents to generalise the findings. Future research can incorporate multiple variables and attributes along with control variables for advanced statistical learning. Furthermore, advanced prediction modelling could be initiated in future to investigate the role of contextual variables. Researchers can even think of bringing design management aspects into the entire process flow methodology to make smart products highly flexible and quality oriented.

Abstract

The case study methodology is a well-established method in operations management; however, clarity lacks on how to determine the number of cases required in multiple cases studies designs. This paper considers how the principle of saturation can help with this important aspect of research design. Saturation is considered at different aggregation strata and leads to rules that can be followed to help ensure both internal and external validity. This paper offers recommendations to identify when empirical data are incomplete from the perspective of saturation. These guidelines will help both novice researchers and more experienced ones, albeit in different ways.

Keywords: Case study methodology; operations management; saturation

1. Introduction

The case study methodology has been widely adopted in operations management. Early advocates included McCutcheon and Meredith (1993), Westbrook (1995), Meredith (1998), Voss et al. (2002), Voss et al. (2002) and Westbrook (1995), because of insight that can be generated and its potential to identify possible further research. There are number of seminal work that explain the works and provide guidance including Yin (1984) [and later editions], Barratt et al. (2011), Fox-Wolfgramm (1997), McCutcheon and Meredith (1993) and Stuart et al. (2002). However, the number of cases it still something researchers ponder about when adopting the case study strategy for a particular project.

1.1. Background and Objectives of Paper

Despite its widespread use, within and beyond operations management, guidance about how to set the number of case studies is scarce and the advice varies. For example, Rowley (2002, p. 20) posits that ‘the greater the number of case studies that show replication, the greater the rigour with which a theory has been established’. This statement leaves the number of case studies open, but it suggests at least two. Eisenhardt (1989, p. 545) claimed that four to ten cases usually work well and states that with less than four cases it is often more difficult to generate theory in complex situations. Miles (1984) suggested 15 cases, whereas Levy (2008) indicated that the number of case studies depends upon the purpose of the study, but did not specify any particular number. These incongruent suggestions provide only a limited answer to the question of how to determine the number of case studies required.
However, a common theme is that the justification for the number of case studies required has been based upon the principle of saturation. Cruzes et al. (2015, p. 1657) suggested that new studies should add to knowledge relating to the prevailing research question, and Eisenhardt (1989, p. 545) referred to theoretical saturation for setting the number of cases, based on the work of Glaser and Strauss (1967). Steenhuis (2015) uses the principle of saturation to show that adding case studies until a high degree of saturation is achieved is the way forward; this is called the iterative-progressive case study method. However, this may result in the need to add case studies, which may exceed the resources available in funded or doctoral research projects. Thus, the following two questions remain that we seek to address in this paper:

- What is the minimum number of case studies that should be examined based upon the principle of saturation?
- What are methods to enhance the saturation for findings of case studies beyond adding additional cases?

1.2. Scope and Outline of Paper

The purpose of this paper is to set out further guidance about the number of case studies based on the principle of saturation for the domain of operations management. Some studies refer to saturation when providing a rationale for the number of case studies. For example, Pagell and Wu (2009, p. 40) claimed that they limited their study to ten case studies, because they reached the saturation point in their opinion; however, they did not provide any evidence for this assertion. Note that they also ambiguously stated that they could not process more cases in one study; hence, it cannot be established whether their decision to limit the study to ten supply chains was instigated by saturation or feasibility, two very distinct and seemingly incompatible reasons. Similarly, Choudhari et al. (2013, p. 463) referred to saturation as justification for adding two more cases, but they did not provide any further detail. Also, in other instances saturation is referred to, but without any clear rationale or evidence. The only exception to this lack of more precise guidance is Steenhuis (2015), but this work does not help research determine how many case studies are needed in advance. To generate this guidance, research in other domains was consulted. Taber (2000) describes an example of the use grounded theory and the concepts of ‘theoretical sensitivity’, ‘theoretical sampling’ and ‘theoretical saturation’. Fusch and Ness (2015) critiqued two qualitative studies for data saturation and concluded that failure to reach data saturation has a negative impact on validity. However, these authors did not provide detail on how to apply the principle of saturation when determining the number of case studies in a research design.

The paper is organised as follows. The next section will elaborate briefly on the case study methodology. This will be followed by a section on the principle of saturation for case studies. The fourth section elaborates how this principle will assist in determining the minimum number of case studies, while a final section concludes with implications for research.

2. Case Study Methodology

Before going into more detail about the case study methodology, the question arises what this approach to research constitutes. In this respect, Yin (1984, p.23), seen as one of the originators of the case study approach, defined the case study research strategy ‘as an empirical inquiry that investigates a contemporary phenomenon within its real-life context; when the boundaries between phenomenon and context are not clearly evident; and in which multiple sources of evidence are used’. This implies that the influence of context...
is seen as playing a pivotal role in the understanding of phenomenon. Corroboration of the emerging interpretation is sought by using multiple sources of evidence; this could be obtained by applying a single method to multiple cases, or alternatively applying multiple methods in one instance (Yin, 1981, pp. 58–59). However, because the way the case study methodology is defined, it is often associated with qualitative research methods; for example, Eisenhardt and Graebner (2007, p. 25) referred to it from this perspective. However, looking at Yin’s definition (Yin, 1984, p. 23) the type of research method is not specified, leading to one wondering how this orientation towards qualitative methods came about. Indeed, it has been noted that case studies may adopt quantitative, qualitative or mixed research methods (Rowley, 2002).

2.1. Brief History
The case study method as a methodology for research appeared at the end of the 1970s and the early 1980s. In one of the earliest publications on case studies, Yin and Heald (1975, p. 372) stated that ‘the case survey method is mainly concerned with the analysis of qualitative evidence in a reliable manner.’ However, in this work the explanation and the example position the case study survey method as a systematic review (see Green et al. [2006, pp. 104-5] for a description of such reviews) rather than an individual study, because Yin and Heald (1975) aggregated findings across studies. Stake (1978, p. 7) advocated case studies as a useful method for exploring theory development and commented that this method would be likely to remain popular amongst social scientists. A further development of the case study method can be found in Miles (1979, p. 591 ff.), which described the development of a framework for innovative public schools based on the investigation of six cases. However, it was Yin (1981) that sets out the case study methodology and more detail was provided in the his book (Yin, 1984). From this point forward, case studies become a widely accepted research strategy across disciplines. Examples include: Eisenhardt (1989) for business and management, Houghton et al. (2013) for nursing, Westbrook (1995) for operations management, Gerring (2004) for political sciences, and Runeson and Höst (2009) for software engineering. The case study approach has been defined as a research strategy Yin (1981, p. 58).

Whilst case studies have gained traction across disciplines, some confusion remains about its meaning and its underpinnings throughout. First, different labels are used that appear to be interchangeable (Hamel et al., 1993): ‘case study’, ‘case study method’ and ‘case method’. Sometimes, these terms hide subtle differences. Is the onus on a single case or limited cases being available or is it seen as a specific approach to the research design? Second, the case study methodology is principally without a specific research method. In this respect, the use of Delphi studies, focus groups, interviews and quantitative data has been reported. Third, the term case study is used for a range of different approaches. For example, Gerring (2004, p.342) attested to action research, field studies, etc., when referring to five different interpretations of the case study methodology, of which two can be found in Yin (1994). Though these points should be kept in mind, these three matters do not impact really on the question of how many case studies are necessary to achieve reliability and external validity.

2.2. Traditions for Case Studies
Early writings gravitated towards propositions. For example, Miles (1979, p. 592) used propositions, partially based on the reduction of variables in a project about processes involved in the creation of three elementary and three secondary public schools, as examples of innovative organisations. This point has been reiterated in more recent
publications, such as Gimenez (2005, p. 318), Starman (2013, p. 40) and Tight (2010, p. 334). However, the latter two tightly were linked to Flyvbjerg’s (2006) rebuttal of critiques. This means that existing or tentative theories can be used for generating propositions, and thus, the case study methodology can also be used for hypothesis testing, as noted by Schurink and Auriacombe (2010, p. 452). A case in point for the latter is Dekkers (2010, 2011) who generated propositions for the impact of outsourcing decision on operational control based on three theories – transaction costs economics, resource-based view and core competencies – and two more propositions derived from reasoning about the impact of the decision. Thus, a first strand of cases studies has focused on hypotheses, either by generating or testing theories.

A second stream sees case studies as a means to generate theory. For example, Andrade (2009, p. 52) referred to this approach when stating that ‘theory must emerge from data, and not from any preconceived hypothesis along a conceptualisation progression’. This grounded-theory approach, in the tradition of Glaser and Strauss (1967), which is based on pure inductive logic, where the new theory is derived strictly from the collected data. In this respect, Eisenhardt (1989, p. 536) intimated that this ‘clean slate’ approach is an ideal, and that in research practice the method is informed by the extant literature and existing theories in the theory-building process. Starting from scratch, as implied by the grounded theory approach, is impractical, because the study’s research objectives, the selection of subjects (or objects), and data gathering require some rationale or preconceived ideas; even Glaser and Strauss (1967, p. 169) encouraged researchers to ‘use any material bearing in the area.’ Subsequently, a number of articles (for example, Bourgeois and Eisenhardt, 1988; McCutcheon and Meredith, 1993; Voss et al., 2002) have suggested the use of a priori constructs to help shape the initial design of theory building research. However, such a priori constructs are only to be considered as tentative, akin Popper’s thinking, and may not be in the resultant theory (Eisenhardt, 1989; McCutcheon and Meredith, 1993). In the end, the higher the level of consistency between the emergent theory and existing theory, the higher the external validity achieved.

2.3. Replication Logic at Heart of Methodology
In the case of multiple case studies, the core of the case study methodology is replication logic to achieve such external validity. This is captured by Gerring (2004, p. 344) who stated that ‘a single unit observed at a single point in time without the addition of within-unit cases offers no evidence whatsoever of a causal proposition.’ Consequently, research using the case study methodology must include the temporal dimension for a single case, or otherwise, compare similar instances of phenomena. A single case study is possible, when it concerns an extreme case, a critical case or a paradigmatic case (Flyvbjerg, 2006, p. 230); in none of these three types will saturation be achieved if studies are restricted to one case. Additional case studies will be necessary to achieve generalisation. If the objective is producing similar results, then this is called literal replication, or when producing predictable results, then it is labelled theoretical replication; note the subtle difference between our statement and Rowley’s (2002, p. 21). In this context, Levy (2008, p. 14) remarks that the latter is particularly evident in the criteria for case selection and logic of interpretation in extreme cases, deviant case strategies and comparative studies (using Flyvbjerg’s [2006, p. 230] wording for consistency throughout our paper). Both literal and theoretical replication aim at extending findings to other groups or settings, not to augment the number of data points to increase the confidence of within-group findings (McCutcheon and Meredith, 1993, p. 246). Thus, replication logic aims at
the generalisation of results, findings and theory, whether through literal or theoretical replication by purposefully adding cases.

Ideally, whereas the number of case studies is determined by replication logic, there is also a trade-off between external validity across cases and in-depth observations for each case. The sufficiency of in-depth observations for each case refers to achieving reliable outcomes. In this respect, Voss et al. (2002, p. 202) note that multiple case studies could reduce the depth of a study when the resources are constrained; for example, this may be the case for doctoral studies. However, multiple case studies may enhance generalisability of conclusions, models or theory, and reduce observer bias as long as each case demonstrates that it meets criteria for quality of research design.

2.4. Analysis of Case Studies

In general, four criteria are used for assessing the quality and the generalisation of conclusions, models or theory derived from case studies: construct validity, internal validity, external validity and reliability (Rowley, 2002). These constructs are not limited to case studies, but are seen as generic criteria for the quality of investigations, for example, by Drost (2011) and (Fitzner, 2007). However, in the context of case studies, external validity can be seen as the generalisation of findings to other settings or systems. The evidence and analysis in multiple case studies supports this generalisation by identifying aspects or features of settings that may influence a phenomena or contingencies within cases with the same purpose. It should be noted that the generalisation of a contextual setting or contingencies across contexts is not known on beforehand when designing the methodology. Cepeda and Martin (2005, p. 855) remarked that external validity also concerns whether conjectures, findings and conclusions are connected to existing scholarly knowledge which implicitly calls for an adequate literature review.

As the case study methodology not just investigates cases, but also analyse the impact of a context on a phenomena related to a case, the analysis should consider different levels. Fox-Wolfgramm (1997, p. 446) mentioned the interplay between contexts in this respect and later (ibid.) indicated multiple levels of analysis. We have called these units of analysis and labelled the levels as context, case and embedded unit of analysis. Figure 1 shows the two units of analysis for holistic case studies. For example, these holistic case studies look at firms as a single unit. When considering parts of a firm, but not the

![Figure 1: Levels of analysis for case studies](image)

![Figure 1: Levels of analysis for embedded case studies](image)
total, an additional unit of analysis emerges, which is called an embedded unit of analysis; see Figure 2.

Nothwithstanding rigour in analysis at different levels, the limited number of objects or subjects implies abductive reasoning. Because case studies are characterised by more variables than the number of instances, this seems unavoidable. Therefore, the variables considered and their causal links imply abductive reasoning, which starts with an incomplete set of observations and proceeds to find the likeliest possible explanations (Dekkers, 2017, pp. 61–3).

3. Principle of Saturation for Case Studies
Whether further efforts for data collection or additional cases are needed could be determined by saturation. This can be defined as the point at which incremental learning becomes marginal to achieve a predetermined research outcome, which Glaser and Strauss (1967, p. 61) called theoretical saturation. Operations management research that has adopted the case study methodology or provided insight into the methodology has mimicked this stance. For example, when discussing theoretical saturation, Ravenswood (2011, pp. 681–2) cited Eisenhardt (1989, pp. 533, 545–6), however Eisenhardt explicitly referred to Glaser and Strauss (1967). In the same vein as Glaser and Strauss, Lincoln and Guba (1985, p. 204) recommended sampling ‘to the point of redundancy.’ Fox-Wolffgramm (1997, p. 447) exemplified this by stating that in her study, codes, themes and patterns began to stabilise two-thirds of the way through data collection in research relating to strategic processes in banks. According to Fusch and Ness (2015, p. 1408) data saturation is reached based on three criteria: (1) when no new information will be obtained through further data collection; (2) when further coding is no longer feasible; and (3) when there is sufficient information to replicate the study. However, it is not clear from their writing whether all these criteria should be met, or that at least one should be satisfied. Andrade (2009, p.48) referred to ‘theoretical saturation’ as ‘theoretical sufficiency’. This was derived from Dey (1999, pp. 116-7), who claimed that theoretical saturation ‘has connotations of completion [and] seems to imply that the process of generating categories (and their properties and relations) has been exhaustive’; note the use of the wording ‘exhaustive’ rather than ‘exhausted’. In this respect, theoretical sufficiency is preferred because, theoretical saturation turns out to be an inflexible expression, while both indicate that the data have been properly analysed.

Saturation is mentioned in articles about the quality of case studies as a prominent criterion, e.g. Cepeda and Martin (2005, p. 862), however, the concept is often not operationalised. Van Aken et al. (2016, p. 6) argue that ‘saturation’ is an instance of the law of diminishing returns and that ‘field tests are intended to produce a ‘saturated body of evidence’ on the pragmatic validity of a generic design’. Morse (1995) indicates that saturation is inconsistently assessed and reported. This means that reporting of saturation should be a prominent feature of publications using the case study methodology.

In this respect, Brod et al. (2009, p. 1268) proposed a saturation grid ‘whereby major domains (topics or themes) are listed along the vertical and each group/interview is listed along the horizontal … Saturation is reached when the grid column for the current group is empty, suggesting that new themes or concepts have emerged. However, the final determination that saturation has been reached is made during data analysis (coding) and documented with a refined saturation grid’. This approach could be applied to case studies and units of analysis, too. Data triangulation can improve construct validity (Rowley, 2002). Data tri-angulation helps ensure data saturation, particularly when triangulation
is based on the use of different research methods which creates rich in-depth data (Fusch and Ness, 2015, pp. 1411–2).

Data saturation for case studies happens at two levels and in the case of an embedded unit of analysis even at three levels, though not necessarily in one study. At the level of the case of the embedded unit of analysis, saturation will be achieved once new empirical data does not yield anymore new coding, or when the case study can be replicated. Saturation at higher levels can be identified when there are no new relevant characteristics that influence phenomena or properties of the studies subsystem or aspectsystem.

4. **Determining Number of Case Studies**

Setting aside how the principles for saturation may influence the research design using the case study methodology, some authors have already provided guidance about the number of case studies. For example, Eisenhardt (1989, p. 545) indicated four to ten cases. However, the choice is context dependant and it is recommended to use the principle of saturation; see Figure 3 for the resultant overview.

4.1. **Replication Logic**

Gerring (2004, p. 343) indicated that at least two cases are needed to make a comparison. However, this means that differences between cases cannot necessarily be replicated. This may concern causal relationships when considering theoretical and literal replication. Thus, at least another case, a third one is needed, to compare findings.

4.2. **Purpose of Study**

In terms of systems theories a case study always concerns a subsystem and a limited number of aspects (Dekkers, 2017). This means that abstraction needs to take place. Timpf (1999) identified three types of abstraction: classification, where properties of the system call for grouping to decrease the number of variables; aggregation, which involved putting together different entities to form a coherent whole; and generalisation, is the application of behaviour derived from one set of entities to another set of entities based upon the existence of similar relationships and elements, but not necessarily all.

---

*Figure 3: Pathways for determining the number of case studies in the case of the holistic approach*
4.3. Unit of Analysis
Case studies can involve either single or multiple cases; and may be holistic (single unit of analysis or embedded (multiple units of analysis) (Yin, 1994). There are thus four types of case study design: single case/holistic (type 1); single case/embedded (type 2); multiple case/holistic (type 3); and multiple case/embedded (type 4). Single cases are akin to a single experiment and are appropriate when the case is special, for example to test a well-established theory where the case is extreme or unique. They may also be used as a pilot in multiple case studies (Rowley, 2002, p. 21). Multiple case studies are preferable as the research outcomes become more robust with more cases. Cases can be selected so that they produce similar results (literal replication) or produce contrasting results for predictable reasons (theoretical replication) (Rowley, 2002, p. 21). There is a distinction between holistic case studies and embedded units of analysis. Figure 3 only looks at holistic case studies. Figure 4 adds considerations for embedded units of analysis.

4.4. Snowball Sampling
Snowball sampling occurs ‘when the researcher accesses informants through contact information that is provided by other informants. The process is, by necessity, repetitive: ‘informants refer the researcher to other informants, who are contacted by the researcher and then refer her or him to yet other informants, and so on’ (Noy, 2008, p. 330). Snowball sampling can be used for identifying cases. Subsequent adding of cases provides two purposes to a study. First, it allows the further development of concepts and new insights. This is particularly aimed at achieving saturation. The work of Steenhuis (2015) points in the same direction, though viewing it as the iterative-pragmatic case study method. Second, additional cases allow the replication of earlier findings. However, this strategy could lead to (unintended) bias in the selection of cases and not necessarily the most suitable cases are selected. This means that snowball sampling can be an effective strategy, but requires studies to carefully consider how recommended cases will contribute to the rationale of the research.

4.5. Other Complementary Strategies
In addition to snowball sampling, other complementary strategies for achieving saturation could be used:
- One alternative strategy is the use of focus groups after findings from the case studies have been inferred. Such is suggested by Fusch and Ness (2015, p. 1410) from the perspective of qualitative research; however, this strategy seems to be less favoured by studies in operations and supply chain management.
- A second alternative strategy is indicated by Eisenhardt and Graebner (2007, p. 27); after examining replicated findings further cases can be explored at a higher level.
of abstraction. Dekkers (2009) adopted this approach when examining innovation practices in a Chinese manufacturer of professional printing equipment; the performance of other Chinese firms in the same sector was used to reason that findings may not be restricted to the original company studied.

- A third strategy is to complement the empirical case studies with published studies. Such will result in fragmented data, because these previously published works may have differing research objectives and reporting. An example is found in Dekkers (2018), when comparing three empirical case studies with five reported case studies on group technology; this allowed drawing more robust inferences for specific themes.

- Finally, studies using the case study methodology for a particular purpose can be pooled. Although technically this should be considered a systematic literature review.

5. Discussion and Conclusions

Qualitative research is not concerned with statistical generalisability and uses nonprobabilistic sampling. The most commonly used samples are purposive (Guest et al., 2006). It is often recommended that the size of purposive samples should be established inductively and sampling should be continued until theoretical saturation occurs (Guest et al., 2006). Data saturation is reached when there is enough information to replicate the study. A failure to reach data saturation has an impact on the quality of the research and hampers content validity (Fusch and Ness, 2015).

In research practice, data saturation and the number of case studies will be often a balancing act. As Fusch and Ness (2015, p. 1413) remarked: ‘there is no one-size- fits-all method to reach data saturation; moreover, more is not necessarily better than less and vice versa.’ So in the case of limited resources, which is a common constraint with funded research and doctoral studies, it may be necessary to limit the number of cases. It is often better to think of data as being ‘rich’ (quality) and ‘thick’ (quantity) rather than think in terms of sample size (Dibley, 2011). The quality of the research can also be improved by obtaining data from multiple sources and applying mixed methods. A saturation grid can help identify the marginal benefit of adding each case. Inevitably, in such studies the principle of saturation implies that one case needs to be added beyond those directly required: one case too far!

Abstract

Digital process innovation—defined as the use of digital technology for process innovation—has recently become a new orientation of manufacturing companies to solve operational problems; however, the actual impact of digital process innovation is still unclear. In this research, we study the actual effect of digital process innovation on organizational performance. We further examine whether the impact of digital process innovation is strengthened if manufacturing firms increase their absorptive capability and their slack resource. This research provides valuable insights into how to effectively implement the strategy of digital process innovation.

Keywords: Digital process innovation, Absorptive capacity, Slack resource

Introduction

Operational problems, such as high-volume inventory, continuously increasing operational cost, operational inefficiency, are usually the concerns of the conventional manufacturing process (e.g., Boston Consulting Group, 2014; Kearney, 2016). Recently, digital process innovation—defined as the use of digital technology for process innovation—has become a new orientation of manufacturing companies to solve such kind of operational problems and has demonstrated its effectiveness. Taking GE Company (d’Aveni, 2015) as an example, it adopted digital technology in the production mode transformation of an engine from the assembly of twenty separate cast parts into direct production of one piece. This saves 75% of the operational cost. Nevertheless, there are some other concerns towards the effect of digitized operational processes. For instance, more energy is required in three-dimensional printing than in the traditional injection molding (Chen et al., 2015). Thus, the actual impact of digital process innovation is still unclear.
In this research, we study the actual impact of digital process innovation on organizational performance. We further investigate operational factors that may exert significant bearing on digital process innovation to enhance a firm’s performance. Specifically, we examine that the impact of digital process innovation is strengthened if manufacturing firms increase their knowledge absorptive capability and their slack resource.

Theoretical Background and Hypothesis Development

Digital process innovation enables firms to promptly and accurately identify customer requirements and preferences and to offer customized even new products that, in turn, better meet customer individual requirements (Armenakis and Harris, 2009; Ye et al., 2007; Judge et al., 2009). This may result in increasing firms’ performance. Hence, we hypothesize that the adoption of digital process innovation can improve a firm’s performance, as shown below.

Hypothesis 1: Digital process innovation enhances organizational performance.

Operational absorptive capacity is referred to the capability of an organization’s operational units to obtain, assimilate and exploit knowledge from external source (Patel et al., 2012). In a company, when its operating unit has absorptive capacity, the unit is more likely to have the ability and flexibility to obtain, assimilate and exploit the information provided by external parties and required for the implementation of digital process innovation, leading to higher organizational performance. Therefore, we hypothesize:

Hypothesis 2: Absorptive capacity of a firm positively moderates the relationship between digital process innovation and organizational performance.

Slack resource is defined as the buffer resource, in excess of the minimum necessary resources for a firm’s daily operation, for coping with environmental uncertainty (Nohria and Gulati 1996). Companies with slack resource are likely to have buffer resource as safeguard to present the risk imposed while implementing digital process innovation, leading to enhanced organizational performance. Thus, we have the following hypothesis.

Hypothesis 3: Slack resource of a firm positively moderates the relationship between digital process innovation and organizational performance.

Methodology

We conducted a longitudinal event study to test the effect of digital process innovation on organizational performance. We focus on manufacturing companies that are publicly listed firms in the Mainland China. Driven by the recent China’s policies such as Made in China 2025 and internet plus manufacturing action (China Daily, 2016), many manufacturing companies have gradually adopted and even have fully implemented the strategy of digital process innovation. Hence, manufacturing companies in the Mainland China are the most proper setting to conduct this study.

We consider digital process innovation as a firm’s official launch of digital innovation initiative for its manufacturing process. Accordingly, we collected the
announcements about the adoption of digital process innovation from Factiva and Wisenews using keywords, for example digital platform, digital channel, digital manufacturing, intelligent manufacturing, additive manufacturing, and three-dimensional or 3D printing. Return on asset is regarded as the performance outcome of the firm. R&D intensity as a proxy for absorptive capability while slack resource is based on inventory level.

Finally, we obtained the relevant announcements from a sample of 168 firms. For these sampled firms, we collected data on return on asset, absorptive capacity and slack resource from the China Stock Market and Accounting Research databases.

Data Analysis and Results
We employed the approach of longitudinal event study to test the causal relationship between digital process innovation strategy and organizational performance. The results show that digital process innovation has a long-term effect on the performance of manufacturing companies. Subsequently, we conducted the ordinary least squares regression to examine the potential moderating effects of absorptive capacity and slack resource on the association among digital process innovation strategy and firm performance. The findings demonstrate that absorptive capacity and slack resource strengthen the effect of digital process innovation on firm’s performance.

Discussion and Conclusion
This research reveals the real impact of digital process innovation on organizational performance in the manufacturing domain and explores the factors to enhance such impact. Specifically, it fills up the gap how to effectively implement the strategy of digital process innovation. This research also provides useful guideline for effective implementation of digital process innovation by considering a firm’s internal absorptive capacity and slack resource.

Abstract

Buying firms belong to two separate networks: the internal network consisting of their subsidiaries, and the supply network consisting of their suppliers. Incorporating three theoretical perspectives: knowledge based view, social network theory and dual embeddedness, this study proposes a model explaining the link between geographic dispersion of those networks, their collocation and performance. We argue that the relationship between geographic dispersion and performance is moderated by collocation of both internal and supply networks. Using a large scale study based on secondary data, this paper offers an understanding of the interplay of internal and supply networks and the effect on performance.

Keywords: Geographic dispersion, supply network, internal network

Introduction

Multinational companies (MNCs) operate through globally dispersed networks of plants in which knowledge is developed and exploited at multiple units. The reason for the existence of multinational companies is their ability to transfer, recombine, and exploit resources through several contexts and between countries (Meyer et al., 2011). Gupta and Govindarajan (2000) argue that a multinational company can be considered “a network of capital, product, and knowledge transactions among units operating in different countries”. MNCs are in a powerful position to access resources and capabilities from several local contexts and assimilate them to create competitive advantages. The broader the dispersion of MNC knowledge activities infers that these companies undertake knowledge related activities in diverse locations. This multiplicity of contexts allows the MNC to tap into knowledge from various knowledge clusters and hotspots (Meyer et al., 2011). Many scholars argued that companies should expand to a foreign country gradually as they accumulate resources and international experience (Zeng et al, 2013).
Global supply chains include MNCs that integrate geographically dispersed processes to gain advantage of diverse location benefits. In fact, supply chains are not just a combination of buyers-suppliers’ relationships but they consist of networks that are spreading globally. Yet, the supply network coordinates not only with the firm as one entity but with its several subsidiaries as well as its headquarters. In fact, Demeter et al (2016) have suggested that, in practice, subsidiaries of buying firms operate as members of two distinct networks: internal network composed of several subsidiaries belonging to the same company, and external supply network identified through information and material flows between different companies that cooperate with each other in a supply chain.

The need to look at supply chains as a network of firms that can collectively achieve better performance, operational effectiveness and sustainable competitive advantage has long been recognized (Choi and Hong, 2002). Yet, empirical research has only recently moved beyond the investigation of the dyadic relationship between the buyer and supplier to that of supply networks (Borgatti and Li, 2009; Kim, 2014; Kim et al., 2011).

Therefore, this study aims at establishing whether there is a relationship with the firm’s both internal (such as plants and subsidiaries) and external (such as suppliers and customers) network as sources of knowledge. This study is concerned with how firms achieve better performance by integrating both their internal and supply networks simultaneously, therefore, a dual view of embeddedness is adopted from the international business literature and transferred into a supply chain management context. To pursue this objective, the paper also draws on the knowledge based view and social network theory to explain how the geographical dispersion of the firm’s networks can be beneficial to firm performance and whether collocation of these networks has any effect on this relationship. In fact, a large number of papers have been devoted to study this relationship (Lu and Shang, 2017) without considering collocation. However, results are still far from being conclusive.

**Literature Review and theoretical standpoints**

*Dual embeddedness*

Embeddedness refers to the extent to which a firm depends on its suppliers and buyers in a specific supply network structure (Nahapiet and Ghoshal, 1998). Embeddedness implies that the firms’ competitive performance can be achieved more easily by the social ties they build with different actors in their social environment (Granovetter, 1985; Uzzi, 1997). The concept of embeddedness indicates the contextualisation of an economic action in ongoing arrangements of social relationships and seizes the contingent nature of the activities of an economic actor taking advantage of being embedded in a bigger social structure.

Embeddedness can be defined in terms of structural, relational, and cognitive aspects (Nahapiet and Ghoshal, 1998). Structural embeddedness stresses on the configuration of an entity’s network of relationships, while relational embeddedness emphasises the role of quality of those relationships (Rowley et al. 2000). It has been claimed that only structural and relational dimensions of embeddedness are meaningful dimensions to examine the advantages of embeddedness because it is hard to operationally distinguish the cognitive aspect from other aspects (Granovetter, 1985).

Previous studies have focused completely on one view, missing a comprehensive view of the role of network embeddedness. Past research proposed several levels of structural embeddedness, containing company level, dyad level, and network level. Kim (2014)’s study showed that the understanding of structural embeddedness and relational
embeddedness must be taken into consideration in the efforts to improve firms’ performance. In fact, the study found that the greater understanding of the supplier positional advantage is critical in the development of the operational performance and the structural position helps to improve the dyadic relationship and exchange between a buying firm and its supplier. Most research focus on the positive effects of embedded relationships (Bellamy et al., 2014); however, some researchers have found many negative effects on firm performance such as opportunism, redundant information, relationship inertia that leads to higher relationship costs and maintenance cost and, therefore reducing the positive impact of relational embeddedness (Uzzi, 1997; Villena et al., 2011; Rowley et al., 2000).

In the international business literature, the term “dual embeddedness” refers to the simultaneous integration of a subsidiary into its internal and external network (Figueiredo, 2011; Meyer et al., 2011). Dual embeddedness studies examine mainly how local market knowledge can be obtained from external networks, and dispersed within the MNC through the internal network of subsidiaries (Andersson et al., 2002; Meyer et al., 2011). Dual embeddedness is also defined as the dual linkages used by the firm to create capabilities to achieve better performance (Ciabuschi et al., 2014). It indicates that subsidiaries simultaneously sustain a positive relationship and efficient communication with both headquarters and local companies in host locations. In this way, the subsidiaries are able to tap into this network of local companies in order to learn about expertise and customers and thus seize local knowledge (Figueiredo, 2011). Then, they use their connectivity within the MNC’s network to convey this knowledge. Subsidiaries have to be sufficiently close to the supply network within the local environment to generate knowledge access and inflows, and simultaneously be sufficiently close to the MNC’s internal network for the knowledge to be successfully transferred and exploited through the MNC (Meyer et al., 2011). This may require proximity and collocation between the units.

Dual embeddedness was also used in studies on either internal or external embeddedness and their effect on subsidiaries’ knowledge (Andersson et al., 2002).

Meyer et al., (2011) has noted that there has been rarely any empirical research studying the simultaneous impact of internal and external network. Most studies has either examined the effect of external or internal network and it is, hence, unclear how geographic dispersion and collocation relate to firm performance. In addition, supply chain management studies rarely consider both internal and supply networks simultaneously and when they do, the context has been primarily limited to manufacturing.

Despite the recognised importance of knowledge sharing in networks, the level of embeddedness of subsidiaries and its outcomes have not received much attention in the operations management literature. In contrast, the international business literature discusses internal integration and notes that greater internal integration creates opportunities for subsidiaries to learn from each other (Ghoshal and Bartlett, 1990; Gupta and Govindarajan, 2000) and thus creates potential further development (Ghoshal and Bartlett, 1990).

This study, therefore, answers to the call for research on dual embeddedness (Demeter et al., 2016) and does so by investigating the relationship between geographic dispersion and performance and the moderating effect of collocation in a set of firms and subsidiaries from the electronics industry.

Knowledge based view
This paper is also grounded on the knowledge based view (KBV) (Grant, 1996; Kogut & Zander, 1993). The KBV places knowledge as the firm's most important strategic resource (Kogut and Zander, 1993). It suggests that because knowledge is embedded within firms and is usually hard to imitate, access to heterogeneous knowledge bases is a major determinant of sustained performance. In addition, the KBV uses the logic of the resource based view (RBV) to suggest that knowledge is a major determinant of competitiveness (Kogut and Zander, 1993; Grant, 1996).

Scholars also propose that knowledge sharing between alliance partners is a major contributor to enhanced competitiveness (Grant and Baden-Fuller 1995). Organizations are repositories of knowledge, the ability to access knowledge and to integrate it effectively is truly a source of competitive advantage.

In line with this, the knowledge-based view of the firm would suggest that collaboration provides access to strategic knowledge (Grant and Baden-Fuller 1995; Grant 1996), and that firm performance is directly linked to building capabilities through interacting with heterogeneous sources of knowledge (Kogut and Zander 1993). Therefore, not surprisingly, knowledge management practices among supply chain partners have attracted much attention (Sangari et al., 2015). The literature suggests that partnerships between buyer and supplier firms are a conduit for knowledge sharing that can result in improved performance along the entire supply chain (Dyer and Nobeoka, 2000; Krause et al., 2007). For example, the literature on supply chain collaboration shows that knowledge from upstream suppliers enhances buyer performance (Flynn et al., 2010). Also, according to Ghoshal and Bartlett (1990), specialized suppliers often possess unique knowledge that enables them to provide good quality products at low prices.

The KBV has been developed as an extension of the RBV and it suggests that in addition to its role in firms, knowledge can contribute substantially to an intangible strategic resource in supply chains as well, so that it can be a source of competitive advantages in supply chain and improved supply chain outcomes (Sangari, 2015).

In addition, the International Business literature has often considered that the rationale behind the existence and foreign expansion of multinationals lies in their knowledge and learning abilities (Kogut & Zander, 1993).

In this paper, geographical dispersion of supply networks and of internal networks are related to knowledge based resources in two ways. First, they affect the conduits through which knowledge based resources can be obtained and shared. Links among the buyer, its suppliers, its customers and its subsidiaries influence the access to knowledge. Second, they affect the heterogeneity of knowledge. This is mainly related to geographical dispersion because knowledge asymmetries highly likely exist among geographically dispersed firms (Lu and Shang, 2017).

Furthermore, research on the KBV of the firm has suggested that social networks facilitate the creation of new knowledge within organizations (Kogut & Zander, 1993; Tsai, 2001). Through the development of network ties, transfer of knowledge develops organizational learning. When different units are connected to each other, a network arrangement provides a flexible knowledge transfer structure that substitutes traditional hierarchical structures.

**Social network theory**

Social network theory (SNT) also adds insights to this paper. The supply chain management research is increasingly examining supply chain relationships beyond the traditional buyer supplier dyad, looking instead on the supply network (Wagner and
Supply chain management is not just dyadic; it actually considers paths through a network of firms. Indeed, previously, the focus has been on paths between just two nodes: supplier to focal firm, and focal firm to buyer. Yet, the concept of suppliers of suppliers and buyers of buyers and so on has at all times been there, and recently, the notion of a supply network is starting to replace that of a simple path. Given that a supply chain is a network of companies and thus comprises several interrelated parties, Choi et al. (2001) stated that social network perspective could be an appropriate approach to study supply networks. Also, many studies in the supply chain management literature have shown the salience of social network analysis to study supply networks (Borgatti and Li, 2009; Kim et al., 2011; Kim, 2014). This stream examines supply chains as complex social networks and uses methods from social network analysis to understand relational ties and their effect on social capital, knowledge transfer, resource access, convergence, and contagion in supply chains.

SNT supports the idea that firms occupying a central network position are likely to achieve better performance due to their access to more information and resources. The more the in-degree and out-degree links a firm has with other units in the network, the higher its node centrality, which in turn leads to a higher access to heterogeneous knowledge. This concept indicates that the more ties a node has the more it is considered as central, thus, when a node is linked to a high number of other nodes, this node has high degree centrality.

More importantly, SNT highlights the effect of lack of connection which is structural holes on buyer performance (Burt, 1992). A buyer who connects disconnected units (i.e. who holds the position of a structural hole) enjoys brokerage opportunities. A hole implies that firms on each side have access to discrete knowledge and information (Burt, 1992). Hence, a structural hole maximizes resource-sharing and knowledge transfer advantages for the buyer. In addition, such benefits to the buyer vary distinctly with the level of connection between its suppliers, customers and subsidiaries. In other words, when the buyer holds a structural hole position, its subsidiary is connected to the buyer’s suppliers and customers, and they, consequently, will allow the connection to their subsidiaries. Therefore, subsidiaries will have the potential to embed themselves within heterogeneous and different types of knowledge networks, in order to accumulate their capabilities required to strengthen their performance and competitive position (Cantwell and Mudambi, 2005).

The relationships between geographical dispersion, collocation and performance are derived from incorporating these three theoretical perspectives, and are more developed in the following arguments.

**Conceptual Model and Hypothesis Development**

In order to access the established and emerging supply markets around the world, firms need to be geographically dispersed. Bode and Wagner (2015) have associated geographical dispersion with the spatial complexity of companies’ supply bases and defined spatial complexity as the extent of the dispersion among members within the network. The geographic dispersion of the supply network has proven to be one interesting avenue on the study of supply networks. Studies that have investigated supply networks’ geographic reach have shown that it has an impact on a number of operational and supply chain goals (Lorentz et al., 2012).

Geographic dispersion in business management studies has been defined in many ways. Miroshnik (2002) describes geographic dispersion as the propagation of companies...
over vast international distances. O’Leary and Cummings (2007) suggest that geographic dispersion has generally been defined in spatial terms, drawing on measures that take into consideration physical distances, number of countries, sites or locations.

In fact, when MNCs are widely dispersed geographically, each subsidiary builds up its own unique pattern of embedded network ties in the host country, therefore, the MNC headquarters encounters a bigger diversity as well as more opportunities to gain advantages from multinationality (Cantwell and Mudambi, 2005).

Narasimhan and Kim (2002) contribute to the above discussion from the supply chain management perspective, by finding evidence on an inverse U-shaped relationship between international market diversification and firm performance whereas Lorentz et al. (2012) suggest a negative relationship between intra-firm supply chain performance and geographic dispersion of sales and purchasing.

In addition, Manuj and Mentzer (2008) suggest that the internationalisation of supply adds complexity, and that “greater supply chain complexity lessens the relationship between supply chain risk strategies and risk-related outcomes”, making management more challenging. Bode and Wagner (2015) studied a sample dominated by large firms and have found a positive relationship between the spatial complexity of the supply chain and the frequency of supply chain disruptions. However, organizations that have a high degree of geographic dispersion are, therefore, able to access and transfer knowledge more effectively from one unit to another, hence, they are more productive than organizations that are less capable of knowledge transfer.

The literature offers two opposite views on the effect of geographic dispersion and performance and the concept of geographic dispersion seems to have trade-offs. However, the KBV of the firm proposes that the benefits of access to knowledge outweigh the potential for opportunism in the collaborations between firms. As a result, we propose the following:

_Hypothesis 1: The geographic dispersion of internal and supply networks of firms has a positive impact on firm performance._

On the other hand, collocation has been widely regarded as an effective way to improve performance (Narasimhan and Nair, 2005). Mechanisms like frequent team meetings, supplier conferences, cross functional teams and collocation are suggested to managers as ways of improving business outcomes (Cousins et al., 2008). In addition, Narasimhan and Nair (2005) define supply chain proximity as “the physical closeness of the buying and supplying firm”. They found that supply chain proximity is positively associated with the formation of strategic alliance program as well as with performance. In fact, buyers who locate close to their customers and who require their suppliers to locate close to them implicitly value the physical proximity because it might enhance their ability to provide superior customer service, better control the flow of materials, better coordinate production schedules or be very responsive to changes in manufacturing demands. Therefore, if this flow of resources and knowledge is enabled through collocation of entities, greater effects on performance can be expected. In other words, with effective knowledge transfer processes in place, suitable knowledge can be channelled most effectively to the proper recipient, enabling a supply chain with a better performance.

Therefore, we hypothesize that:

_Hypothesis 2: Collocation of internal and supply networks moderates positively the relationship between geographic dispersion and firm performance._
Design/methodology/approach
The geographic breadth and depth of a firm's multinational network are used as indicators of geographic dispersion. The breadth is measured by the number of foreign countries in which the buyer has at least one subsidiary whereas the depth is captured by the number of subsidiaries per foreign country. Collocation is captured by the number of suppliers and customers being collocated with buyers and their subsidiaries in the foreign countries. Firm performance is captured by return on assets, return on equity, and return on sales.

The hypotheses will be tested using a sample of firms in the electronics industry. The focus is on electronics because this industry has moved from being controlled by large companies like IBM, HP and Toshiba into an industry where companies have significantly developed global networks (Bellamy et al., 2014). Further, an industry such as electronics embodies aspects such as high market unpredictability, short product lifespans, and globalization (Sodhi and Lee, 2007). Secondary data for this paper is being collected from Bloomberg and Orbis, a financial database that includes information about more than 250 million companies around the world.

Conclusion
In this paper, a research model is derived from incorporating three theoretical perspectives: dual embeddedness, knowledge based theory and social network theory. Although, a big portion of supply chain studies has focused on geographical dispersion of supply network, but the question “What is the impact of collocation on the relationship between geographical dispersion and performance?” did not receive any consideration in the empirical literature. Driven by this question, this proposal aims to extend the literature in three main ways. First, empirical metrics will be used to measure the geographical dispersion, collocation of networks and performance and, an empirical investigation will explain the direct and moderating effect of the hypotheses. Second, this study will answer the call for research on dual embeddedness of a buying firm in its supply and internal network. Finally, this research is one of the first studies that considers collocation of dual network and its effect on performance which is an under-researched subject in the supply chain literature.

Abstract
Whereas lean production is widely adopted in industry, there is a gap in the current literature regarding studies that consider implementation of lean production from a regional context. Hence, this study addresses the impact and contingencies of regional context on the implementation of lean production. More specifically, the results of two case studies in Romania are presented and discussed. Data collection included in-depth semi-structured interviews as well as observations of processes. The results show that using four dimensions of regional context does influence the implementation of lean production and the operational performance of the company.

Keywords: Lean production, regional dimensions, case study

Introduction
Lean production has been widely implemented by companies in different regions with the aim to improve performance. However, the impact of regional context when implementing lean production remains a gap in the literature (e.g. Bortolotti et al. 2015, Bhasin 2013). Few studies (e.g., Hines et al. 2004) that have looked into this issue lack sufficient in-depth analysis. Therefore, this study sets out to investigate in detail the impact that regional context may have on the implementation of lean production.

Research Objectives
Thus, this study aims at asserting the influence of the regional context on the implementation of lean production. It has become apparent that a few number of firms that adopted lean production, which relates to organisation culture (Bhasin 2013). In this
respect, regional context covers what members of society share and what leads to behaviour of the people, i.e. employees, suppliers and managerial mind (Wiengarten et al. 2015). More generically, some (e.g. Yadav et al. 2010) assert that firms struggle with implementing the concept of lean production, thinking that Toyota’s success lies in their cultural roots and, hence, the concept is not transferable. However, Toyota has been successful in multiple countries, and not only Japan. Moreover, some (e.g. Kull et al., 2014; Wangwacharakul et al., 2014; Wang, 2008) have noted that the implementation of the concept of lean production varies for different regions, albeit without going into much detail. This study will address the gap about the adoption of lean production in regional contexts. Hence, the study addresses three research review questions:
1- To what extent the regional context contingencies affect the implementation of lean production as set of practices.
2- Are regional contexts a contingency for the design of lean production system?
3- How the regional context differs from a company to another?
To answer these questions, two case studies have been investigated in Romania, including an in-depth interviews and observation.

Outline of Paper
This paper is structured as follows. First, the literature review, which includes lean production and the regional context, is presented. Next, the methodology section, followed by an analysis of the papers. After that, there is a discussion of the findings. Then at last, conclusion of the study.

Literature Review
Before looking at the regional context, is necessary to look at what the concept of lean production constitutes. Although Womack et al. (1990) were the first researchers to propagate the conceptualisation of lean production, they never gave a specific definition for ‘lean thinking’. This lack of definition in literature about lean production has reverberated until today, as Petterson (2009) notes. The only ones that have given a more specific description (rather than definition) of lean are Shah and Ward (2007), who have mentioned that lean production is about socio-technical system. However, even lean production practices and principles vary; some researchers list as few as five principles (Womack & Jones 1996), whereas others list over twenty practices or principles with more details for every aspect (e.g. Kull et al. 2014; Shah & Ward 2003; Shah & Ward 2007; Yadav et al. 2010). This implies that the concept of lean production is relatively undefined.

Hence, this lack of definition for lean production offers a unique opportunity to evaluate literature; the distinction of two strands of research into lean production serves as base for the further analysis. Therefore, this section of the paper will look with more detail into two different lenses: (i) lean production as a set of practices, (ii) lean production as design of production systems and to the regional context.

Two Lenses for Lean Production
The first lens, lean production as a set of practices, considers the process that a firm follows for implementing lean production, its methods, and tools, and practices. The practices can be defined as ‘an activity or action which is performed to a standard which is better or equal to the standard achieved by other companies’ (Davies and Kochhar 2002, p. 290). The tools that can be applied on Just-In-Time, total quality management, kanban, total preventive maintenance (e.g. Flynn et al. 1995; Shah & Ward 2003; Shah & Ward
2007). Lean practices lens is what most studies are addressing, what are those practices, what should be considered fundamental practices for implementing the lean production.

More specifically, some studies categories practices for lean production (e.g. people, process, tools). Shah and Ward (2003) grouped the practices into four categories: Just-In-Time (JIT), total quality management (TQM), total preventive maintenance (TPM), and human resource management (HRM), while this has 22 lean practices. Rahman et al. (2010) enumerate 13 practices out of the practices identified by Shah and Ward (2003) and they have grouped them in four categories. Moreover, Shah and Ward (2007) divide 10 factors into supplier-related, customer-related and internally-related (the process inside a firm). Chavez et al. (2013) describing the internal lean practices that is mostly used on a shop floor of a firm, in another word hard practices and its effect on other dimensions such as quality and flexibility. Several studies have addressed lean practices in a different way by dividing them into two: soft practices and hard practices, such as (Kochan & Lansbury (1997); Rahman & Bullock (2005); Shah & Ward (2003); Yang et al. (2011)). Whereas, soft practices are focusing on people, for example, managerial practices and relationships (i.e. continuous improvement, top management leadership, and customer and supplier involvement), hard practices are concerned with technical and analytical tools, for instance, statistical process control and Kanban (Bortolotti et al. 2015). The latter also noted that the reason that most companies struggle with adopting lean production or getting the success they are looking for, resides mostly in ignoring soft practices and applying only the hard practices. Some practices may not be suitable for other region’s employees; in this respond, Oudhuis and Olsson (2015) noted that regional differences should be taking in to account before implementing a production system. This all indicates that contingencies related to regional context may have a noticeable impact on the implementation of lean practices.

The second lens concerns the application of lean production principles (Bhasin 2012) to the design of production systems. For example, Low et al. (2015) study how to apply the lean principles to the design of a factory. In this strand of research, some studies use the principles for designing the firm, whereas (Black 2007 and Sobek II et al. 1999) fall back on the ‘pure’ Toyota production system. In addition, there are studies mentioning the lean principles for production as key to the design of production system (Black 2007; Mund et al. 2015; Low et al. 2015; Sobek II et al. 1999; Yadav et al. 2010). According to Yadav et al. (2010), the Toyota production system can be captured by four basic rules: (i) activities (how people work); (ii) connections (how the people connect); (iii) how the production line is constructed (pathways); and (iv) continuous improvement. According to Low et al. (2015), there are 11 key principles for lean production and the core is reducing the non-value-adding activities.

Some studies addressed applying the different principles on different regions without generalisation of the regional contexts such as Low et al. (2015) and Yadav et al. (2010). On the other hand, Sobek II et al. (1999) believed that applying the design principles of the Toyota production system is not related to the regional contexts. This all points to the necessity for evaluation whether contingencies related to the regional context have an impact on the design of production system.

Regional Context
For both lenses - lean production as a set of practices and lean as design of production system – contingencies related to the regional context need to be further specified, four dimensions could serve as initial classification (Aldossary et al., 2016). More specifically, the distance between a supplier and a manufacturing company to expand the most benefits from JIT (Cook 2001); also Arkader (2001) mentioned the location as barrier to JIT.
Culture differences between two nations (Wangwacharakul et al. 2014) or different cultural perspectives in an organisation, which includes the employees’ relations and issues; which leads to cultural dimension. Another dimension concerns that get in the way of doing the business or smoothing the flowing of goods from a location to another or from a supplier to a company, as few studies described it as regulation and certificates (see Maleyeff et al. 2012; Rodgers & Wong 1996), which can be named as legislative dimension. Finally, considering the different ways that an organisation can look at its financial performance that may be a challenge in the implementation, as well as not having the right investment to help with the implementation change (Ketokivi & Schoeder, 2004), which can be linked to a financial affect. The geographical, cultural, legislative, and financial-economic dimensions can serve as classification of contingencies within regional context.

Research Methodology
Given the limited literature on this topic, and with the aim to achieve a deeper understanding of the effects related to regional context on the implementation of lean production, the study applied an exploratory multiple-case study methodology (Creswell 2003; Yin 2009). According to Eisenhardt (1989), case studies are useful when the phenomenon has not yet received appropriate ascertainment within the literature and when theoretical knowledge lacks clearness with respect to underlying issue. Moreover, multiple cases may help to understand the meaning and nature of real-life events, such as processes, relations and changes on organisational and individual levels (Yin, 2009).

In this respect, and for the explorative purpose aimed towards understanding, the empirical data for the case studies was collected through multiple methods and sources (Miles & Huberman, 1994; Yin, 2009). These included mainly semi-structured interviews and observations. Multiple interviews with top management and shop floor employees were conducted which lasted between 60 and 75 minutes. The interview data were supplemented with data collected through secondary sources, such as, project documentation, company guidelines, and web sites, and observations during the guided tours in the companies.

Case Study R1
The first empirical case (R1) concerns a manufacturing company in the aerospace industry. The company is in the medium size range with number of employees between 200 to 300 employees. R1 was founded in 2010 and the design of lean production was implemented from the beginning, adopted since they are a subsidiary of a conglomerate. Company R1 a full-service company includes extrusion, machining, and assembly into a single facility. Which serve customers all over the world from the far west as the United states to the far east Japan and China.

The value chain process followed by the company involves five main steps: (i) billet casting, (ii) extrusion, (iii) machining, (vi) surface treatment, and (v) assembly. In those steps for the analysis of the case study, they were assessed and investigated based on the dimensions mentioned before. Taking in perspective the plant size of the company, which almost includes three plants in one, which are the main three extrusion, machining and assembly. The delivery time of the company if the external suppliers are not involved the time is 8 days, however, when external suppliers get involved the time varies with no certainty.

Case Study R2
The second empirical case study (R2) is also a company in the aerospace industry, they focused on overhaul. Also, the company is a medium-sized company with the number of
employees being between 200 and 300. The company started implementing lean production with aim to cut waste, identification of internal benchmarks and giving ideas and concepts for specific problems. Therefore, they are using five steps of the product line; starting with (i) the product comes in to the plant, (ii) the company assessed the product, (iii) orders placed for needed parts, (vi) components get reassembled, and finally (v) components are shipped back to the customer. The delivery time varies in between minor to major remanufacturing on the unit. The delivery time from the unit register to the plant to the time of leaving the facility ranges between 3 months to 18 months.

Results and Findings

The analysis followed the general thematic analysis approach indicated by Braun and Clarke (2006): i) familiarisation with data, ii) coding, iii) searching for themes, vi) reviewing themes, and v) defining and naming themes. Interview and focus group transcriptions were coded, checked and rechecked throughout the coding process for consistency. Whereas some themes were already latently found in literature discussed at the previous section, the analysis of the data gave rise to additional themes. The themes were reviewed and re-categorised resulting in to four main themes (Table 1), also can see Aldossary et al. (2016). The following sections will discuss in detail the findings of each dimension. The themes also

Geographical Dimension

The geographical dimension, is concerned with the location of companies, location of suppliers being in a cluster (Porter 1998), the relationship between the company and their supplier, and any geographical barriers related to the implementation of lean production. Whereas company R1 can manufacture all the necessary parts in site, there are cases when it is required to order these from external suppliers. More specifically, there are certain customers who may require from R1 to use specific external suppliers. These suppliers can be based in different places either in the U.S. or in Europe, consequently, R1 faces constant challenge with time deliveries. For example, a delivery to the US may take up to six weeks, which exceeds standards of R1 of time deliveries to customers. Similarly, is the situation when a shipment goes to the far East (e.g. China).

Company R2 manufactures some parts, meaning that their inventory level has certain parts that are used commonly. However, when it comes to certain parts related to the core of engines, these are all supplied from two external suppliers based in central-west Europe. These two suppliers, based in different countries, will have to be involved for the remanufacturing of one component. As a result, depending on the condition of the unit received, the delivery time from the external suppliers can take 2-3 months for minor remanufacturing and up to 18 months for major remanufacturing. As a senior manager of R2 explained, that makes it very hard to meet the delivery time; mainly because most of the times the suppliers will take longer time in delivering the parts.

Hence, due to geographical proximities, both companies R1 and R2 are facing challenge with the delivery of parts. In company R1 the main issue appears to be the distance, and for company R2 distance as well as uncertain delivery coming from suppliers’ contingent on the state of parts. Finally, both companies are also affected by the poor infrastructure of the region they are based in; which can significantly increase the lead-time for logistics.

Cultural Dimension

The second theme concerns the cultural dimension which is focusing on the employees’ behaviour towards lean implementation. In the case of R1, from the beginning
of the company’s found the company was designed to implement lean production system; and therefore, the employees did not go through any transformation period. Irrespective, it is important to note that R1 operates in the north of Romania. Specifically, in this part of the country, people have a high level of education, and at the same time, they are very family-oriented meaning that employees prefer to work close to their hometown with most of them willing to do so, even if it means there will be less pay. This is clear in the case of R1 where more than 90% of the employees come from the same region. But the company is having very skilled and well-educated employees, due to the strong family oriented mind-set in this part of the country, businesses do not operate during the weekends. That means that R1 is not able to receive or send deliveries of parts during the weekends, which reduces the flexibility to respond to logistic perturbations.

Opposite to first case, R2 did not have a lean production system from the beginning, and therefore, when the management decided to implement lean production practises and lean design of production system, all the employees had to go through a transformation period. As a result, management faced challenges with employees accepting the change. As a senior manager explained, it has taken a lot of time and effort to smoothly transit to lean production and even now (at the time of the interview), they are still dealing with some negative attitudes from employees who find this system more demanding.

**Legislative Dimension**

The third theme, legal dimension, is mainly related to certification of some aerospace parts and the intellectual property agreements that the companies must obey. This means that without the necessary agreements, the company cannot produce certain parts they need. The legal dimension also concerns with the legal agreement that links each company with suppliers overseas. These legal issues contribute on the factors that affect the implementation of lean production. Whereas, companies R1 and R2, have this dimension as a contingency on the implementation of lean production, the legal factors are recognised as a way for controlling in this industry. For instance, in R1 there are fixed contracts with certain customers indicating that the customer’s suppliers must be used on producing a product to that customer. Furthermore, they are certifying the products and some parts the companies R1 and R2 produced by the top customers in the industry.

**Financial Dimension**

The fourth and final theme, financial dimension, concerns the investment of implementing lean production and the plants’ layout. In this regard, company R1 has invested heavily on the plant, and they are expanding the volume of production for the plant to reach its full capacity. Moreover, R1 is planning strategically to have another plant ready when the capacity of the first plant hits the maximum. At the same time, also tries to have duel source of producing all the parts needed to cut their costs and save time. However, the extrusion part of the company is in full capacity, and it causes delays to the other parts of the plant such as assembly line.

In Company R2, the case is slightly different. The budget for investing on the design of the production system is very limited, and the company tries to develop year by year. The flow of the units is not as smooth as it should be, but the company is making the most of the resources they have. Despite all the shortages in budget regarding the design, R2 is functioning is high-quality outputs.

The results of the two case studies confirm that the regional context does have an impact on the implementation of lean production. For instance, the cultural dimension within company and country shows a variety of aspects that have an impact on the implementation, such as; the employees’ acceptance of change. Moreover, from the
geographical perspective, it is shown that the location of suppliers plays a considerable role in the implementation of lean production since both companies had first-tier suppliers abroad. Also, looking at the financial dimension of the companies, the support for the transformation of the production system varied from one company to another. Finally, the analysis of the legislative dimension in this study revealed challenges regarding intellectual property rights; more specifically, exclusive suppliers that were holding these rights for certain parts impeded on the flow of the production line, as the parts are only allowed to be produced from certain company.

In comparing the two cases, cross-case analysis was used to identify similarities and differences. Table 1 shows the findings of each case as well as the cross-case analysis of the two cases conducted.

### Table 1 cross-cases analysis of contingencies related to regional contex

</table>
Discussion of Findings

The first finding of this study is related to the financial investment of R1 and R2 on the design of the lean production operation system and the layout of the plant. In R1 the philosophy of was introduced when the company was founded; therefore, the company is accustomed to the system from the beginning, as well as having the footprint set for the production system. In the case of R2, the company started implementing lean production in 2012, and due to poor financial support they had a limited design developed to have the best design of the production system. The R1 has very slight disruption in the flow of the products, where the reason relates to the full capacity reached of the extrusion part of the plant and the unadjusted machines in the machinery side of the plant. However, in R2, the disruption in the flow of the units is caused due to the design structure not being on the highest standard, and not having considered and included all the necessary aspects as discussed by Black (2007) and Sobek II et al. (1999). Hence, the financial dimension plays a crucial role and more specifically, the limited investment affects in a high degree the design of the lean production system and therefore the operational performance of the companies.

The second finding concerns the effect of the geographical dimension has on the implementation of lean production. The location of the suppliers and ease of the supplier access play huge role in the success of applying the lean production. It was found that JIT is the practice mostly affected by the supplier access and location. For instance, company R2 is dealing mainly with two main external suppliers outside of Romania, which proves to be as one of their biggest challenges causing shortages in delivery time and delays. The situation is slightly different in company R1, it goes mostly the other way around which is the delivery to the customers. In both cases, once the supplier is located outside of the country and with the weekend work restrictions, that makes the impact on this dimension more tangible on the implementation. Therefore, the geographical dimension is found to be a barrier for successful implementation of lean production practices such as JIT, Kanban and Kaizen. This finding of the role of geographical dimension on the lean production practices supports the findings in literature of Cook (2001, p. 967) and Arkader (2001, pp. 91-2). Moreover, according to the analysis of the data gathered from both case R1 and case R2, it is evident that the role of the geographical dimension is the most challenging one for successful implementation of lean production.

The third finding is related to the organisational and regional culture. Our findings agree with the suggestions of Bortolotti et al. (2015) and Semeds (1994) that the organisational culture of a company may have significant effect on the successful implementation of lean production. More specifically, in case R2 the management faced the challenge of having the change to the lean production system. The acceptance is not easy from the employees’ side. The company had to face some issues they have dealt with in some ways as they explained. Moreover, regarding the cultural dimension, the people who live in the north part of the country tend to be more educated and family oriented, who does not prefer to be working away from their hometown. As a cultural background of Romania with some ties of the religious beliefs, the weekends in the country is blocked, the companies R1 and R2 are affected by this, as they are unable to make deliveries during the weekends.

The fourth and final finding in this study is about the legal dimension and how it may affect the implementation of lean production. The two companies mainly dealing with companies for the parts needed. Some of the companies are involved in certifying a product to be sold to top customers. Furthermore, some of the top customers relate their suppliers to be in link with Company R1. For example, if R1 want to have business with one of the leader in the industry, that customer requires R1 to deal with all materials...
needed from the same supplier they deal with. Company R2 on the other hand, the suppliers they deal with are externals, and they are the ones who certify the R2 products based on legal ties. The reasons for having the connection only with these external suppliers is the intellectual property (IP) holders for certain parts; and therefore, the parts must come from them. Hence, whereas it is acknowledged that this dimension may affect in some degree the implementation of lean production, the companies have little to no control on most of the legal issues.

The four findings of this study show how regional dimensions can have different effects on the successful implementation of lean production. It is concluded that the most dominant regional dimension with the highest degree of effects is found to be the geographical dimension and the one with the least important effects is the legal dimension; it has effect but it could be mitigated.

Conclusion

The results of the case studies show that successful implementation of lean production is affected by dimensions related to the regional context they operate in. Therefore, this investigation study overcomes shortcomings of previous studies that have not considered this in sufficient detail. Hence, the conjectures and findings add new insight to the current literature. These findings are expected to give direction to managers about the successful implementation of lean production using the four dimensions.

Abstract

This paper aims to explain mechanisms that enable firms to manage the contradictory forces of co-opetition (i.e. simultaneous cooperation and competition) to achieve superior operational performance in business ecosystems. Since the benefits of co-opetition are not always straightforward, we intend to prove empirically the effects of co-opetition on operational performance through two mediators: absorptive capacity and supply chain agility. Data from 214 international firms in Tech-Cities were collected to test the hypotheses through regression analysis with bootstrapping. Results show that co-opetition is associated with higher levels of absorptive capacity and supply chain agility, which relate to superior operational performance.

Keywords: Co-opetition, supply chain agility, absorptive capacity.

Introduction

Co-opetition, defined as the simultaneous pursuit of cooperation and competition (Bengtsson and Kock, 2000; Brandenburger & Nalebuff, 1996; Luo, 2007), has received growing interest among scholars and managers over the past few years. Indeed, Luo (2007) posits that firms enhance performance through the advantages of both cooperation and competition. For instance, co-opetition has become a popular practice within the automobile industry where many traditional competitors such as Toyota, BMW, Peugeot, and Citroën have collaborated to share resources, develop new technologies or grow the market to obtain superior results compared to solely competing with each other (Ritala et al., 2014). However, the benefits of co-opetition are not always straightforward. Co-opetitive relationships are complex and they involve many risks since this practice literally means “sleeping with the enemy” (Bengtsson and Raza-Ullah, 2016). In fact, the paradoxical nature of co-opetition, which involves two co-existing and contradictory forces, generates co-opetitive tensions (Bengtsson, Raza-Ullah, et al., 2016). Due to the relative difficulty of balancing the dual forces of cooperation and competition, scholars suggest examining the dynamics underlying co-opetitive relationships (Wu, 2014) in
order to guarantee a firm’s superior performance. Nevertheless, empirical evidence on the effects of co-operation on performance are scarce (Quintana-García and Benavides-Velasco, 2004). Most studies have largely focused on innovation, financial or market performance, showing mixed results: both negative and positive (Park et al., 2014; Le Roy and Czakon, 2016). Regarding operations management research, although literature agrees that co-operation has positive effects on cost reduction, quality standards, product efficiency or flexibility (Luo, 2007), the impact of co-operation on operational performance has not been tested thus far.

Consistently, we question whether there is a mechanism through which firms can manage the contradictory forces of co-operation to achieve superior operational performance. According to the literature, firms require certain capabilities to effectively manage a co-operative relationship (Gnyawali et al., 2016). Among these capabilities, scholars suggest that absorptive capacity is beneficial in co-operative relationships (Bengtsson and Raza-Ullah, 2016; Dorn et al., 2016; Wu, 2014) since knowledge can be obtained, assimilated, transformed, and exploited effectively (Zahra and George, 2002) to gain competitive positions in inter-firm networks. According to Ritala et al. (2013), absorptive capacity determines the extent to which firms can create value from co-operative relationships. Yet, empirical evidence on the effectiveness of co-operation is needed (Dorn et al., 2016). Similarly, agility has been identified through exploratory case studies as a key capability to deal with the challenges of co-operation (see e.g. Bengtsson and Johansson, 2014). Specifically, supply chain agility is crucial to managing inter-organizational relationships and improving competitiveness in operations (Swafford et al., 2006). However, the effects of co-operation on supply chain agility for improving operational outcomes have not been empirically demonstrated.

This study utilises a relatively recent perspective based on collaborative management capabilities (Dorn et al., 2016) to examine the effect of co-operation on operational performance. Specifically, it proposes absorptive capacity and supply chain agility as mediators in the relationship. Both capabilities are viewed by the literature as critical sources of competitive advantage and superior performance (Christopher, 2000; Liu et al., 2013; Zahra and George, 2002) when firms collaborate with other partners. To test different hypotheses, data were collected from 214 international firms hosted in two Tech-Cities and regression analysis with bootstrapping was used.

Our research enriches the co-operation literature in several ways. Firstly, it is one of the first papers to introduce the concept of co-operation within the operations management field. Secondly, it examines the “black box” or mechanisms by which firms can simultaneously compete and collaborate to obtain superior operational performance. Finally, it shows that co-operation is a suitable collaboration strategy in order to build and increase a firm’s absorptive capacity, which in turn transforms other operational capabilities such as supply chain agility to achieve superior results in operations.

The remainder of the paper is organized as follows. First, we present the theoretical background and hypotheses. Second, we explain the methodology employed, followed by the results and the discussion of these results. Finally, we address managerial implications, the limitations of the study and directions for future research.

**Literature review and hypotheses**

Co-operation was coined in the 1980s by Ray Noorda, founder of Novell, to describe a paradoxical relationship that involves two contradictory forces: cooperation and competition (Bengtsson et al., 2016). Recently, co-operation has gained attention for its positive effects on cost reduction, quality standards, product efficiency and flexibility, among other benefits (Luo, 2007; Morris et al., 2007; Ritala and Hurmelinna-Laukkanen, 2013; Zahra and George, 2002).
2009). Many real-life examples and case studies of companies have recently proven that collaboration with competitors is, in fact, a successful collaborative strategy for relevant areas of a firm’s operations. For instance, the collaboration between Sony and Samsung to create joint technology and manufacturing facilities in South Korea enabled them to become market leaders in the LCD TV segment (Gnyawali and Park, 2011). The result ended up with the development of high quality products, reduced development time, cost sharing and risk reduction. However, in the operations management literature, the impact of co-opetition on performance has not been tested so far. In an attempt to measure these effects we examine operational performance in terms of quality conformance to specifications, delivery speed, delivery dependability, cost, volume flexibility, and product mix flexibility (Hallgren and Olhager, 2009).

Through cooperative relationships, firms are able to share costs, information, knowledge and access to complementary resources (Bengtsson et al., 2010; Dussauge et al., 2000), while competition improves efficiency, increases innovativeness and forces firms to remain active in order to gain a competitive position (Bengtsson and Kock, 2000; Porter, 1990). Therefore, firms collaborate to jointly improve performance in some areas, and then compete in other areas to enhance their own performance (Luo, 2004). If, according to theory and some case examples, co-opetition enhances areas of firms’ operations such as reduced costs, shorter lead times, product efficiency, flexibility or quality standards (Gnyawali and Park, 2011; Luo, 2007), then it may translate into positive effects for firms’ operational performance. As a result, a firm that is capable of leveraging the dual benefits of co-opetition might exhibit higher operational outcomes. Thus, we propose the following hypothesis:

H1. Co-opetition is positively related to operational performance.

Moreover, absorptive capacity can help to explain how co-opetition efforts are translated into superior operational performance. First, partnerships with competitors improve learning and capability acquisition, especially from partners with complementary resources (Dussauge et al., 2000). Particularly, collaboration with competitors becomes more valuable since rivals operate in common contexts, confront analogous problems, satisfy similar needs, possess related knowledge and use similar technologies (Dussauge et al., 2000; Ritala and Hurmelinna-Laukkanen, 2009). Second, firms do not only maintain collaborative relationships with competitors to acquire new knowledge and skills from partners (Luo, 2007), but also to create and develop other capabilities through the intensive exploitation of existing ones (Quintana-García and Benavides-Velasco, 2004). Although there is a risk since the same knowledge used in cooperation could be used for competitive purposes (Gnyawali and Park, 2009), Cohen and Levinthal (1990) indicated that the negative appropriability incentive associated with spill-overs might be counterbalanced by a positive absorption incentive. Firms must ensure that the benefits of co-opetition exceed the costs associated with knowledge spillovers. Therefore, firms maintaining co-opetitive relationships are involved in a race in which those achieving higher absorptive capacity remain on the winning side (Wu, 2014). As a result, through co-opetition firms enhance their knowledge base and skills, and they learn how to increase their current level of absorptive capacity (Gnyawali and Park, 2009). Finally, firms with high levels of absorptive capacity are better able to apply renewed knowledge in order to identify business opportunities (Liu et al., 2013). By leveraging new knowledge with existing knowledge, and then incorporating it into operations, firms may exhibit higher performance results. Therefore, we suggest the following hypothesis:
H2. Absorptive capacity mediates the relationship between co-opetition and operational performance.

Despite the above, additional variables may further explain the relationship between co-opetition and operational performance. Specifically, through exploratory cases studies, Bengtsson and Johansson (2014) identified agility as one of the three interrelated capabilities to deal with the challenges of co-opetition in SMEs. In today’s challenging global markets and unpredictable environments, agility is a capability that must be understood beyond the reach of the individual company. According to Hoek et al. (2001) firms should work together within the supply chain to achieve the desired level of agility. Consistently, we focus on the role of supply chain agility, which refers to a firm's ability to effectively collaborate with partners to respond to market changes in a speedy manner (Liu et al., 2013; Swafford et al., 2006), and this may also include competitors.

On the one hand, the literature has identified various benefits of co-opetition, such as the reduction of costs, uncertainties, and risks, superior quality standards, shorter lead times, greater speed in product development, improvements in product efficiency and product innovation, the achievement of scale economies, stronger market positions, and access to complementary resources (Gnyawali and Park, 2009; Luo, 2007; Morris et al., 2007). These advantages are closely related to the three critical processes of the supply chain—procurement/sourcing, manufacturing, and distribution/logistics—described by Swafford et al. (2006). Moreover, firms that implement co-opetitive strategies improve flexibility (Quintana-García and Benavides-Velasco, 2004), which is broadly considered by the literature as an antecedent or prerequisite for agility (Bernardes and Hanna, 2009; Swafford et al., 2006). On the other hand, supply chain agility may help to ensure superior operational performance when firms collaborate with competitors. First, supply chain agility can be seen as a critical mechanism for dealing with co-opetitive costs—technological risks, management challenges, and the loss of control (Gnyawali and Park, 2009). Second, it enables the firm to mitigate disruption risks, to react in a speedy manner to marketplace changes and other uncertainties, and to achieve superior competitive position (Braunscheidel and Suresh, 2009; Swafford et al., 2006). Finally, when firms collaborate with competitors, agility becomes essential in building and reconfiguring their relationships over time (Bengtsson and Johansson, 2014). Consequently, supply chain agility is a critical factor in responding effectively and efficiently to operational changes, and improving performance outcomes (Liu et al., 2013). As a result, we posit the following hypothesis:

H3. Supply chain agility mediates the relationship between co-opetition and operational performance.

In addition, absorptive capacity may also be effective for increasing a firm’s levels of supply chain agility. Particularly, knowledge is one of the main ingredients for building a firm’s agility. Agile firms continually marshal the necessary knowledge and assets for seizing market opportunities (Bernardes and Hanna, 2009). Moreover, according to Dove (1999), having the right knowledge in the right place at the right time through knowledge management is a key enabler for agility. In that sense, high levels of absorptive capacity ensure external knowledge acquisition to reengineer firms’ processes and exploit new opportunities that are present in the environment (Cohen and Levinthal, 1990). As a result, firms can adapt and respond rapidly to marketplace changes to ensure supply chain agility. When firms collaborate with competitors, agility allows them to build and reconfigure relationships over time in order to sustain their opportunities (Bengtsson and
Johansson, 2014). Eventually, firms achieve superior competitive positions through supply chain agility (Swafford et al., 2006), leading to enhanced performance (Chen and Chiang, 2011). Therefore, we propose that absorptive capacity has an indirect effect on operational performance by shaping supply chain agility. In this sense, absorptive capacity and supply chain agility sequentially mediate the effect of co-opetition on operational performance (i.e. serial mediation):

H4. The relationship between co-opetition and operational performance is serially mediated by absorptive capacity and supply chain agility.

Method
We tested the effects of co-opetition on the dependent variable, operational performance, with two serial mediators — absorptive capacity and supply chain agility — through a three-path mediation model depicted in Figure 1. The model is assessed using regression analysis with bootstrapping. Specifically, hypotheses were tested using the PROCESS macro for SPSS, which is widely used (Hayes, 2013) in the social and business sciences for estimating direct and indirect effects in single and multiple mediator models.

Data were collected from 214 firms hosted in two Tech-Cities located in Spain. Altogether, these Tech Cities account for more than 1,100 member organisations, which therein defines our target population. We developed a survey questionnaire with a seven-point Likert scale for each construct and some specific questions to measure control variables. The measurement scales for the variables were adapted from earlier studies to fit the specific context of this research. Only the scale for co-opetition was developed specifically for this study since Bengtsson and Raza-Ullah (2016) called for the development of new measurements that capture both the intensity and the similarity dimensions of cooperation and competition. Our final scale has six items based on a literature review on co-opetition. CFA analyses performed with EQS 6.1 guaranteed the psychometric properties of all of the measures.

Results and discussion
The present study develops an integrated model to explain how co-opetitive relationships in business ecosystems work within the field of operations management. Specifically, we empirically examine the operational performance implications of both absorptive capacity and supply chain agility for co-opetitive relationships in business ecosystems. We used the approach developed by Hayes (2013) to test the hypothesized relationships in a three-path mediated model. The model with all the estimates of the path coefficients is illustrated in Figure 1.

On the one hand, we analysed the direct effect of co-opetition on operational performance through H1, which stated that co-opetition is positively related to operational performance. However, the results of the regression analysis showed no significant effect for the direct relationship ($\beta = 0.003, SE = 0.036, n.s$), thereby rejecting H1. This result is consistent with a previous study that found that horizontal collaboration had a non-significant effect on firm performance (Robson and Bennett, 2000). Therefore, although co-opetition seeks to obtain the positive-sum effects of simultaneous cooperation and competition, there are several costs associated with this specific type of collaborative strategy that may impact the achievement of significant outcomes. According to Gnyawali and Park (2009), these costs are with regards to the risks of technological leakage, loss of control and exceptional management challenges. Similarly, Bouncken and Fredrich (2012) claimed that co-opetition has two faces: it can foster performance but at the same time it is associated with opportunism risks and misunderstanding among...
parties, which in turn can undermine performance. In that sense, although co-opetition is considered an opportunity to increase operational outcomes through improved products and services, cost savings or shared resources, it simultaneously offers these same opportunities to competitors (Le Roy and Czakon, 2016). Thus, firms may not develop or sustain a competitive advantage over their competitors. Consequently, the direct effects of co-opetition on operational performance are unclear and its positive effects can be counterbalanced by the costs associated with co-opetition. Therefore, we might be missing the underlying mechanism through which co-opetition effectively influences operational performance.

On the other hand, we examined the indirect effects through the three-path mediation model with regard to H2, H3, and H4. H2 stated that absorptive capacity mediates the relationship between co-opetition and operational performance. The significance test required the prediction of an indirect effect of co-opetition on operational performance through absorptive capacity. According to the results, the effect is significant (β = 0.021, SE = 0.011, p<0.001), thereby supporting H2. Moreover, co-opetition predicted absorptive capacity (β = 0.140, SE = 0.057, p<0.014) and that absorptive capacity predicted operational performance (β = 0.148, SE = 0.067, p<0.029). Therefore, our findings suggest that only when firms develop strong absorptive capacity can they realize the dual benefits of cooperation and competition to obtain superior operational performance. First, collaboration with competitors eases external knowledge acquisition due to a common language and similar processes amongst competing firms (Wu, 2014). A rival’s knowledge is more relevant for the firm since it is the basis of differentiation among competitors (Ritala and Hurmelinna-Laukkanen, 2009; Wu, 2014). Even if opportunistic behaviour is a concern, the competitive pressure means firms remain alert to knowledge spill-over. Moreover, the negative appropriability incentive may be counterbalanced by a positive absorption incentive (Cohen and Levinthal, 1990). Therefore, absorptive capacity is essential to guarantee a balanced situation among the strategic resources and capabilities that firms acquire from rivals and those that they provide. Second, co-opetition allows the firm to develop its current levels of absorptive capacity by integrating new knowledge from competitors. High levels of absorptive capacity ensure relevant knowledge is acquired and utilized effectively and probably faster than by competitors, which in turn provides a superior competitive position for the firm within its business ecosystems. Finally, having the right knowledge at the right time allows for making better operational decisions. In addition, by utilizing knowledge, firms can improve previous processes or develop new skills to enhance operational outcomes. As a result, firms collaborating with competitors obtain superior operational outcomes through the development of absorptive capacity.

H3 established that supply chain agility mediates the relationship between co-opetition and operational performance. On the contrary, the significance test that requires the estimation of an indirect effect of co-opetition through supply chain agility on operational performance was non-significant for that relationship (β = 0.010, SE = 0.026, n.s.). As a result, co-opetition is shown to have no significant effect on supply chain agility, and therefore we reject H3. Although many benefits of co-opetition are related to the three critical processes of the supply chain—procurement/sourcing, manufacturing, and distribution/logistics—described by Swafford et al. (2006), co-opetition offers the same or similar opportunities to competitors. Moreover, since competitors operate at the same horizontal level they might share common suppliers. Thus, although suppliers may support firms with information regarding new technologies, products or services, or by giving advice on cost reduction (Robson and Bennett, 2000), improving agility through the supply chain, etc. competitors can also easily access the same benefits. All of this
provides no competitive advantage over competitors within the same business ecosystem networks. As a result, our findings suggest that the development of supply chain agility is not sufficient and does not guarantee superior operational performance when firms maintain collaborative relationships with competitors.

Finally, H4 stated that the relationship between co-opetition and operational performance is serially mediated by absorptive capacity and supply chain agility. The indirect effects of co-opetition on operational performance through the mediation of absorptive capacity and supply chain capability were shown to be statistically significant ($\beta = 0.016, SE = 0.008, p<0.001$). Moreover, co-opetition is associated with both higher absorptive capacity ($\beta = 0.140, SE = 0.057, p<0.014$) and supply chain agility ($\beta = 0.219, SE = 0.072, p<0.003$), which relate to higher levels of operational performance ($\beta = 0.522, SE = 0.103, p<0.000$); therefore, H4 is supported. When a firm collaborates with competitors, it can acquire valuable knowledge since competitors pursue similar goals and interests. Moreover, similar knowledge bases with competitors facilitate the rapid acquisition and exploitation of knowledge in specific applications (Ritala and Hurmelinna-Laukkanen, 2013; Wu, 2014). This fact allows the firm to better understand how competitors operate and improves its ability to absorb knowledge. Furthermore, due to the competitive pressure, firms seek to improve their existing level of absorptive capacity in order to successfully integrate knowledge and exploit it faster than competitors. According to Ritala and Hurmelinna-Laukkanen (2013), firms with capabilities to manage knowledge exchanges effectively will be able to create a better basis on which to build on further technologies, concepts or capabilities. Specifically, absorptive capacity ensures appropriate knowledge to create a shared understanding with other partners in business ecosystems. As a result, firms can synchronize and better understand the market and other partners' activities in order to improve the overall agility of the supply chain (Liu et al., 2013). In this way, firms achieve superior competitive positions within business ecosystems since agility allows them to build and reconfigure relationships over time in order to sustain their opportunities (Bengtsson and Johansson, 2014). By improving agility in the critical processes of the supply chain (i.e. procurement/sourcing, manufacturing, and distribution/logistics; Swafford et al., 2006), firms can experience higher operational results. Therefore, collaboration with competitors has positive effects on operations through supply chain agility, but only when it is...
indirectly affected by absorptive capacity. Previous studies are consistent with our results proving a positive effect of absorptive capacity on supply chain agility (see, e.g. Liu et al., 2013). In summary, absorptive capacity ensures renewed knowledge to better understand the market, which in turn promotes sufficient agility to effectively face up to the contradictory forces of co-opetition and obtain superior operational results.

### Conclusions

The theoretical implications of the research are threefold. First, it enriches the co-opetition literature by extending its influence into a firm’s operations. In particular, it is the first paper that empirically proves the impact of co-opetition on operational performance through the indirect effects of two serial mediators (i.e. absorptive capacity and supply chain agility). Second, our research examines some of the mechanisms or the “black box” by which firms can simultaneously compete and collaborate to obtain superior operational performance within a business ecosystem context. Specifically, the research shows that co-opetition is a suitable collaboration strategy in order to enhance a firm’s absorptive capacity, which in turn transforms other operational capabilities such as supply chain agility to achieve superior results in operations. Finally, we have provided and validated a new scale for measuring co-opetition. Overall, our research leads to a better understanding of the mechanisms that enable operational outcomes to be realized when firms maintain collaborative relationships with competitors in business ecosystems.

Our results are also significant for managers whose firms belong to business ecosystems. First, managers who are reluctant to collaborate with competitors should consider the potential value of co-opetition beyond the risks associated with this practice. In complex and uncertain environments, such as business ecosystems, firms cannot stand alone to meet up to the challenges they face; thus they seek out co-opetitive partnerships (Bengtsson and Kock, 2000; Bengtsson and Raza-Ullah, 2016). Particularly, since competitors pursue the same goals and face similar problems, through co-opetition firms can achieve performance levels that no single firm could create alone (Peng et al., 2012). Second, in these large networks, co-opetition is a common practice. Thus, managers should be aware of the possible effects that this strategy implies for the firm’s outcomes. As collaborating with competitors generates different sorts of tensions (Bengtsson et al., 2016) compared, for example, to supplier collaboration, managers should lead a firm’s efforts towards the development of organizational processes and routines related to external knowledge identification, acquisition, integration and exploitation. This will give them an advantage over competitors to utilize a rival’s knowledge faster than them. By using external knowledge, firms can make better decisions and gain a better understanding of the market and of other relevant partners. As a result, firms are better able to effectively collaborate with partners to respond to market changes in a speedy manner (Braunscheidel and Suresh, 2009; Liu et al., 2013; Swafford et al., 2006). This in turn will allow the firm to increase supply chain agility. Lastly, co-opetition can help the firm to improve operational performance by obtaining several benefits, such as cost reductions, superior quality standards or shorter lead times. However, managers should consider that without the development of capabilities for knowledge absorption, the benefits of co-opetition for supply chain agility and for firm operational performance will not be realized.

Finally, when interpreting the results of our study, some limitations must be taken into account. First, the use of cross-sectional data limits the cause–effect relationships that can be inferred from the results. Since business ecosystems are constantly evolving, future research could examine the relationships analysed using longitudinal data to understand more aspects of co-opetition in these complex networks. Second, the questionnaire is
limited to two Spanish tech cities. Thus, the generalizability of the findings to other international tech cities may be limited. Future research should consider carrying out similar studies in tech cities located in other countries. Finally, we investigated the possible benefits of co-opetition for a firm’s operational outcomes. However, we did not compare this collaborative strategy against other types of collaboration that do not include competitors (i.e. collaboration with suppliers, customers, etc.). Although the literature agrees that firms obtain higher benefits through balanced-strong co-opetition than pure cooperation or competition (Quintana-García, Benavides-Velasco, 2004), an empirical comparison of co-opetition with other collaborative strategies for firms’ operational performance has not been undertaken to date.

Abstract
Empirical investigations of how Industry 4.0 technologies affect outplacement patterns are sparse for medium-sized enterprises. This paper contains an empirical analysis of how industry 4.0 technologies affect cost driven outplacement of production based on 191 full and useable answers to a questionnaire-survey distributed in 2018. The paper builds on data revealing that companies’ pursuit of cost-focused competitive strategy positively associates with moving production abroad. However, data also shows that the more Industry 4.0 ready decision-makers are, the less do cost-focused strategy drive production outplacement. Furthermore, perceived barriers towards Industry 4.0 technologies promote cost-driven outplacement whereas perceived drivers decrease cost-driven outplacement.

Keywords: Location of production, drivers, barriers, readiness, Industry 4.0

Introduction
The globalization of trade has led to increased pressure on Western-based manufacturers to be competitive. According to Porter (1985), firms pursue competitive strategies based on either cost leadership or differentiation. From a production perspective, manufacturing strategies must be aligned with the corporate strategy and thus also the competitive strategy (Skinner, 1969; Wheelwright, 1984). Western companies have experienced increased competition for companies manufacturing in low-salary countries like Asia and Eastern Europe. This development has pushed to development to outplace production in low-cost countries to remain competitive. Drivers for outplacing production have been much researched and cost considerations has been identified among the most prevalent motives (Contractor et al., 2010; Jahns et al., 2006; Mihalache and Mihalache, 2016).

This paper has its main focus on the cost motive for outplacing production since this is the most common. However, it should be emphasized well that other motives exist, such as proximity to markets and customers, access to knowledge and access to new technology
In literature, there is a demand for focusing on firm size in the location of production issues, especially small and medium-sized enterprises (Arlbjørn and Mikkelsen, 2014). According to the EU Commission (2015), a medium-sized enterprise has between 50 and 250 employees, a turnover between 10 and 50 million Euro and a balance sheet total between 10 and 43 million Euro. Compared with large enterprises, medium-sized (as well as smaller) enterprises typically have fewer resources and experience in managing new technologies, CEO involvement in daily operations and having a dominating operation focus at the expense of strategic and development-oriented activities (Zach et al., 2014).

Recently, the literature on using advanced technologies often referred to as Industry 4.0, has increased intact with industrial diffusion. The discussion of such technologies is both applied in connection with avoiding production to move abroad and to be used as a driver for moving production back to original high-cost home destinations (e.g. Arlbjørn and Mikkelsen, 2014; Fratocchi et al., 2016; Tate, 2014). However, a recent literature review reveals a lack of empirical founded research on the application of Industry 4.0 technologies (Liao et al., 2017). This is supported by Castelo-Branco et al. (2019) who demands more research on the adopting of the various Industry 4.0 technologies in production processes. Furthermore, there seems to be a biased view on these technologies towards multinational enterprises (MNEs) (Liao et al., 2017; Mittal et al. 2018; Moeuf et al., 2018). SMEs often display a lower IT and Industry 4.0 readiness compared with MNEs due to e.g. lesser resource availability (Haug et al., 2011; Schumacher et al., 2016). The apparent lack of SME based studies towards smart manufacturing/Industry 4.0 indicates a research gap within the current scientific body of knowledge (Mittal et al., 2018).

Based on the discussion above, the purpose of this paper is to advance the understanding of the relationship between SMEs degree of strategic cost focus and the location of production as moderated by managers’ perceptions of drivers, barriers, and readiness for Industry 4.0 technologies. More specific the paper pertains to the discussion of whether Industry 4.0 technologies may affect decisions on the relocation of production.

Conceptual frame of reference

Industry 4.0

The term Industry 4.0 originates from the German “Industrie 4.0” invented in 2011 in Germany as a Federal Government initiative to strengthen the competitiveness of the German manufacturing industry (Hermann et al., 2015). Industry 4.0 is an umbrella term for a number of different technologies that function in a cyber-physical system such as 1) big data and analytics, 2) autonomous robots, 3) simulation, 4) horizontal and vertical system integration, 5) internet of things (IoT) (including sensors), 6) cyber-security, 7) the cloud, 8) additive manufacturing, 9) augmented reality, 10) artificial intelligence, 11) mobile technologies and 12) RFID and RTLS technologies (Ruessmann et al., 2015; Saucedo-Martínez et al., 2018).

Academic literature on the relocation of manufacturing with an emphasis on Industry 4.0 technologies has grown in interest during the last years. Fratocchi et al. (2016) and Tate (2014), for example, refers to the reduced cost of robotics as a driver for moving manufacturing back to high-salary cost countries where labor extensive jobs could be automated. Tate and Bals (2017) point out that the rise of automation and robotization with little or without human intervention is driving companies to re-evaluate their shoring decisions. Benstead et al. (2017) discuss automated machinery as a reshoring driver. Thus, Industry 4.0 technologies may be viewed as a driver for relocating production.

Readiness for Industry 4.0

According to Lokuge et al. (2019) readiness theory is concerned with the “readiness for
change” as a precursor to a successful implementation. It describes a state of being fully ready to engage in a specific activity. In other words, readiness is a state that is attained prior to the commencement of specific activity in relation to psychological, behavioral, and structural preparedness of the organizations (Lokuge et al., 2019). Haug et al. (2011) and Stentoft et al. (2019) suggest that Industry 4.0 readiness consist of the following dimensions: 1) pressures to change existing processes; 2) willing to take risks with the technologies; 3) having sufficient knowledge about the technologies, 4) having support from top management, 5) having employees with the right competencies, 6) having employees with the right motivation to work with the technologies and 7) having economic freedom to work with Industry 4.0.

New technology and the location of production
Extant literature on location of production have included the use of new technologies and automation of production as a potential lever for location decisions (Arlbjørn and Mikkelsen, 2014; Stentoft et al, 2016a; Tate, 2014). Investments in new technologies might prevent companies to outplace production and/or bring production back to home-destinations after previously have been moved abroad. However, research has shown that the readiness for such technologies still needs to be developed and especially for SMEs (Castelo-Branco et al., 2019; Stentoft et al., 2017, 2019).

Accordingly, we hypothesize that:

H1: Strategic cost-focus in SMEs associate positively with moving production abroad
H2: SME managers’ perception of strong readiness for Industry 4.0 weakens the relationship between strategic cost focus and moving abroad
H3: SME managers’ perception of strong barriers for Industry 4.0 strengthens the relationship between strategic cost focus and moving abroad
H4: SME managers’ perception of strong drivers for Industry 4.0 weakens the relationship between strategic cost focus and moving production abroad

Method
To test the hypotheses, we use questionnaire-survey on Danish SME manufacturers with between 50 and 250 employees. The survey was distributed in April and May 2018. Using the Danish company database “Bisnode”, an initial list of 3.400 manufacturing SMEs was identified. Cleaning the list for companies without contact information, and companies that appeared on the list by error, the net list of companies was reduced to 2.632. Each company was first approached by phone, asking for the person responsible for business development, and asking for an agreement that the respondent would attend to a link to the questionnaire-survey, which was sent beforehand by e-mail to the respondent. Reminder e-mails were sent several times during April and May 2018. 736 companies agreed to attend the questionnaire-survey. Out of these, 191 provided full and useable answers on survey items concerning production out-placement, giving a response rate at 26.0%.

Measures
Dependent variable
With an interest in how industry 4.0 may have changed firms’ dispositions to outplace production, our interest is in firms’ recent as opposed to historical outplacement activities. As Industry 4.0 technologies are at a rapid pace of development, we decided to focus on outplacement activities over the recent three years only. The outplacement variable was assessed from the questionnaire item: “Has your company in the past 3 years taken production abroad?” [No=0; Yes=1].
Independent and moderating variables

Low-cost strategy orientation was measured on a five-point Likert scale questionnaire item: “To what extent is your competitive strategy cost-oriented (competing by cheaper prices)?” [1: very little; 5: very much]. Perceived readiness for industry 4.0 was measured using a scale developed by Haug et al. (2011). Seven 5-point Likert scale questionnaire items here combine into a one-factor solution (Appendix A), which explains 53.95 % variance, and with a Cronbach’s alpha value of .852. We construct the Industry 4.0 readiness index as the average score of the seven items. Perceived barriers for industry 4.0 was assessed using eleven 5-point Likert scale questionnaire items (see Appendix A) (Stentoft et al., 2019). Factor analysis confirms a one-factor solution, which explains 48.88 % variance, having a Cronbach’s alpha value of .890. The industry 4.0 barriers index was constructed as the average score of the eleven items. Perceived drivers for industry 4.0 was assessed using eight 5-point Likert scale questionnaire items (see Appendix A) (Stentoft et al., 2019). Results from the factor analysis show a one-factor solution, which explains 45.46 % variance, and reliability analysis shows a Cronbach’s alpha value of .826. The industry 4.0 drivers index was calculated as the average score of the eight items. Interaction terms between low-cost strategy and the three Industry 4.0 indices are calculated based on standardized values.

Control variables

Several controls were employed. First, we controlled for firm size using the number of employees, and we control for firm age measured by numbers of years since the firm was founded. Firm size as well as firm age has previously been associated with decisions to outplace, as well as take back production (Arlbjørn and Mikkelsen, 2014; Roza et al., 2011). Also, we control for the firm’s international engagement in terms exporting, measured by the firm’s exporting as a percentage of turnover. Previous studies have shown a positive relationship between firms exporting and their propensity to outplace production. We also control for firms’ innovation strategy, asking of the extent to which the firm pursues a proactive innovation strategy (single item, 5-point Likert scale). This is from the recognition that both low-cost and innovation strategies may provide a motive for outplacement of production (Fratocchi et al., 2016; Johansson et al., 2019; Stentoft et al., 2016b) – as well as for taking production home (Di Mauro et al., 2018; Srai and Ané, 2016; Stentoft et al., 2016b). In the interaction models specified below, we further include controls for the interaction between the three industry 4.0 variables (readiness, barriers, and drivers), and the proactiveness of firms’ innovation strategy, thereby considering that the industry 4.0 context may similarly affect the association between firms’ innovation strategy and production location decisions.

Analyses

To analyze how production outplacement associate with firms’ low-cost strategy and perceptions of industry 4.0 readiness, barriers, and drivers, we used logistic regression. The self-report nature of the survey data raises the potential concern for common method bias (Podsakoff and Organ, 1986). Harman’s single-factor test using all perceptual variables from the regression model produces a one-factor solution explaining 27.2 % of the variance, which indicates that common method bias is not a problem. Moreover, common method bias is generally considered less of a worry when interested in individuals’ subjective perceptions, such as in the case of the industry 4.0 barrier and industry 4.0 driver variables. The concern is more prominent when perceptions are used as indices for more objective measures, such as if had the industry 4.0 readiness construct been used to indicate firms’
actual capacities to engage in industry 4.0 technologies and business models. Similarly, because common method variance can severely deflate interaction effects making them more difficult to detect (Siemsen et al., 2010), we contend that common method bias is likely to be small and not likely to affect the results.

**Results**

Table 1 shows the means, standard deviations and the correlations for the variables included in the study. Outplacement of production associate positively with low cost strategy, firm size, exporting, and proactive innovation strategy, as expected. There are no significant correlations between outplacement and any of the industry 4.0 variables. The correlation table is the low correlations among the independent variables, which signifies that the risk of multi-collinearity is low.

Table 2 presents the results from the logistic regressions on outplacement of production. Model 1 presents the results from the main-effects model without the industry 4.0 variables included. The result support hypothesis 1 that low-cost strategy associates positively with outplacement of production. Results also suggest that proactiveness in firms’ innovation strategies relates positively with production outplacement decisions – and that this association is somewhat stronger than the association between low-cost strategies and production outplacement. These direct effects remain significant as the industry 4.0 variables are included in model 2.

</table>
For low-cost strategy, the odds ratio is 1.925 (p=.012), signifying that the odds of outplacing production become almost two times higher with a one standard deviation increase in the strategic low-cost focus. Similarly, the odds ratio 2.117 for Industry 4.0 barriers, implies that the odds of outplacing production slightly more than doubles with a one standard deviation increase in perceptions of industry 4.0 barriers. The coefficient for Industry 4.0 drivers is negative but insignificant. The sign of the Industry 4.0 readiness coefficient is positive, but here again, the effect is insignificant.

Including the industry 4.0 variables in model 2 significantly increases the explanatory power of the model with Pseudo R2 increasing from 17.16 % to 25.50 %. This confirms our expectation that the industry 4.0 context has a bearing on production outplacement decisions. Nonetheless, of the three Industry 4.0 variables, only the negative effect from Industry 4.0 barriers is significant, signifying that SME managers’ perceptions of high barriers to engaging with industry 4.0 technologies seem to encourage production outplacement decisions. In Hypothesis 3, we specified this relationship specifically for firms pursuing low-cost strategies. The results here indicate that perceptions of high industry 4.0 barriers also have a general effect in promoting production outplacement decisions.

Model 3 shows a significant negative interaction effect between low-cost strategy and industry 4.0 readiness. This result supports Hypothesis 2 that firms who pursue a low-cost strategy will be less inclined to outplace production when they perceive high readiness for industry 4.0. In turn, this is an indication that industry 4.0 technologies have the potential to strengthen firms’ cost structure for their domestic operations. In model 4, the coefficient for Industry 4.0 barriers is positive as expected from hypothesis 3. Yet, the coefficient is insignificant, and hence leave no support for the expectation that firms pursuing low-cost strategies will be more inclined to outplace production when they perceive high barriers to engage with industry 4.0 technologies. In model 5, the negative and significant interaction term between low-cost strategy and industry 4.0 drivers supports hypothesis 4. The higher the low-cost focus of a firm, the more perceptions of high industry 4.0 drivers will tend to decrease the propensity of the firm to outplace production. In model 6 (the full model), the positively moderating effect from industry 4.0 readiness on the relationships between low-cost strategy and production outplacement remains significant turns insignificant. Opposite, we here see a moderately significant positive moderating effect from Industry 4.0 barriers.
The negative moderating effect from industry drivers on the relationships between low-cost strategy and production outplacement remains significant. Hence, results in model 6 support hypothesis 4, moderately supports hypothesis 3, yet do not support Hypothesis 2.

The marginal effect plot (see Figure 1) shows that the marginal effect of Industry 4.0 drivers on the effect from low-cost strategy is significant for the lowest 69% perceptions of industry 4.0 barriers (i.e. up until half a standard deviation below the mean) and decreasing with lower perceptions of drivers. At the mean perception of industry 4.0 barriers, the marginal effect is 9.3%, increasing to 12.6% at the 16 percentiles (1 standard deviation below the mean), and further increasing to 14.6% at the 2.3 percentiles (2 standard deviations below the mean).

Figure 1 - Marginal effects of Industry 4.0 drivers and barriers

Figure 2 shows that marginal of Industry 4.0 barriers on the effect from low-cost strategy on production outplacement is significant from the mean score, and upwards. At lowest 16 percentile, there is a 4.2 percentage marginal change in the probability of outplacement. At the mean perception of industry 4.0 drivers the marginal effect is 6.3%, increasing to 12.6% at the top 84 percentile (1 standard deviation above the mean), and further increasing to 16.8% at the top 2.5 perceptions of industry 4.0 barriers (2 standard deviations above the mean). These results show that how managers perceive industry 4.0 drivers and barriers have quite considerable effects on how SMEs weight decisions of whether to pursue low-cost strategies by producing abroad or at home.

Discussion

The analyses in this paper reveal several interesting results. First, data support the relationship with a company’s strong strategic cost focus and the outplacement of production to low-cost countries. Thus, in times where reshoring has received more awareness, a cost pressure still exists, which may put pressure to move production abroad to low-cost countries. However, operating with a cost competitive strategy may continuously stimulate a cost reduction focus in the supply chain and thus also for the manufacturing part. Such strategies can explain the reshoring activities where production is not moved back to home destinations but to other destinations from e.g. China to other Asian countries due to increased salary and welfare costs or to Eastern Europe due to lower total costs in terms of e.g. shorter transport distances, improved quality, and reduced management costs. Thus, costs are a major decision factor in location decisions of production which supports past research.

Another interesting result is that SME managers’ readiness for Industry 4.0 dampens the effect of a strategic cost-focus on the outplacement of production. This result provides empirical evidence for past research contributions that on a theoretical level have mentioned the use of Industry 4.0 technologies as a mean to hinder some production to move abroad or
might be a driver for reshoring to home-destinations (Arlbjørn and Mikkelsen, 2014; Fratocchi et al., 2016; Tate, 2014; Tate and Bals, 2017). The result also supports the findings from the questionnaire-survey by Stentoft et al. (2016a), which showed that companies working with a higher level of technological supply chain innovation (in terms of digitalization, new process technologies such as additive manufacturing and automation and robotization) to a higher degree keep production domestic or backshores to domestic facilities. However, the industry 4.0 umbrella is wide why there still need research to be carried out that investigate which technologies that might be most appropriate under which circumstances. Manufacturing companies are different along a number of parameters why potential benefit and the antecedents for applying the technologies might be different.

This paper’s analysis contains also the SME’s perception of the drivers as well as the barriers relationship with a strategic cost focus and outplacement of production. The analysis shows some support that the more perceived barriers there exists towards Industry 4.0 technology, the more a cost focus drives outplacement. In contrast, data reveal with strong support that the higher the perception of Industry 4.0 drivers, the lesser the degree by which a cost-focused strategy will lead to outplacement of production. As the present utilization of Industry 4.0 technologies in general still is modest (Stentoft et al., 2017, 2019), one can find inspiration in Industry 4.0 maturity models to increase the knowledge level and thus reduce the barriers (Mittal et al., 2018). From a policy perspective, the lack of standards, the shortage of experts with the necessary skills and public policies could also areas to improve to reduce the barriers for SMEs (Castelo-Branco et al., 2019).

As a contribution to previous studies, the results from this study suggest that the identified industry 4.0 effects on production outplacement pertain to cost-driven motives. Analyses of how an innovation motive to outplace production associate with Industry 4.0 finds that companies that moves abroad based on an innovation perspective is not affected by Industry 4.0 technologies.

Conclusion
This paper has set out to analyze how cost driven outplacement of production is affected by SME managers’ readiness and perception of drivers and barriers of Industry 4.0 technologies. The paper provides empirical data from Danish medium-sized manufacturers and reveals that companies that pursue a high degree of a cost competitive strategy are more dispositioned to outplace production to obtain low manufacturing costs. Overall, findings suggest that cost-driven outplacement of production are dampened by firms’ Industry 4.0 readiness and perceived drivers of Industry 4.0, while promoted by perceived barriers to Industry 4.0.

These results have both theoretical and practical implications. For theory, this study indicates that Industry 4.0 technologies may affect decisions on the location of production. However, Industry 4.0 is a wide umbrella term, where there is a need to make detailed analyses for the single technologies. For practice, in terms of the companies and governments, these results indicate a need to invest resources to obtain a better knowledge level of industry 4.0 technologies in order make conscious and competitive decisions for where to locate production. Investing in Industry 4.0 technologies may hinder further manufacturing jobs to move out and may provide the basis for bringing jobs previously moved out back again.

Finally, the paper is not without limitations. First, data has only been collected by a quantitative method, why future research can explore this phenomenon further by a number of data-rich case studies. Second, data has been collected by using a single respondent at each company, why future research may include multiple respondents in each company. Finally, data is analyzed among Danish firms who are amongst the forefront OECD countries.
concerning digital adaption (OECD, 2017) and among the most Industry 4.0 ready countries in EU (Castelo-Branco et al., 2019). Thus, future research can expand this study to other nations in order to make such comparisons.

Localisation within the global supply chain: Evidence from the sporting goods industry

Keywords: Localization, Sustainability, Cricket bats

Topics: Global Operations and Strategic Sourcing, Operations Strategy, Sustainability in Operations and Logistics

Wordcount: 5033

Abstract:
The following paper explores issues of localisation, from both an international and local perspective. Initially the paper draws from literature discussing localisation within the context of the global supply chain, showing awareness to change focusing of development purely focused upon the company receiving and selling the finished good. The review identified that attention of the work is primarily focused on the food supply chain and the development of heavy industries. Using case data collected from both India and England form the cricket bat supply chain, the paper shows the different approaches and focus given to development across the locations. Interestingly, craft manufacturing skills are sustained in both locations, as a necessity in India but as a competitive priority for the English manufacturers.

Purpose:
The prevalence of operating within a global network of suppliers and customers has become so embedded within operations management research that is the accepted approach to operating. Even new, small organisations are able to tap into global networks of suppliers to source not only low cost generic components but complex, highly specialised finished goods (Mangan et al. 2010). This has created a whole field of research looking at factors affecting how global supply chains can be designed to enable focal firms (even small ones) to be able to compete in terms of price and functionality on a global stage. However, this perspective had tended to focus upon the global supply chain from the perspective of the focal firm, and how the global supply chain allows such firms to compete. The work has unfortunately paid less attention to organisations within the supply chain, or not until they start creating problems for the focal firm (Frankental 2004). In such situations, a lack of attention, combined with unscrupulous activities can lead to significant reputational risk (BBC 2014).

This raises the need to reframe perspectives on global supply chains in terms of their sustainability (Cerchione and Esposito 2016). However, in their review of sustainable supply chains, Seuring and Müller (2008) still overlooked the role of local manufacturing completely. Within their more recent review of sustainable supply chain management, Koberg and Longoni (2019) also overlooked the impact of localising production on sustainability issues. Conversely, broader research suggests there are significant gains to be made from focusing developments at a local level (Baines 2014, Lee et al. 1993), in terms of local employment and performance improvements, respectively. To address this oversight in the literature, the following paper provides an assessment of selected literature focusing on localisation within a global supply chain context. This is used to direct the analysis of a unique global supply chain (Cricket bats), where manufacturing is both located locally (in the UK) and globally (focusing on India) with products sold in a single market.
The following section reviews a selection of literature on global supply chains, that also gives attention to localisation in order to motivate the research question. This is followed by a summary of the research methods, before presenting data on the companies involved in the research. The paper ends with discussions and conclusions of the research, in terms of how the different firms focus development to create competitive advantages that build upon their operating context and choices they have made related to manufacturing.

**Literature Review:**
While the idea of sourcing cheap, high quality raw material or components from around the globe has considerable appeal to a firm, Svensson (2001, p.15) suggested this was more of a "managerial utopia" that an operational reality. Global supply chains can create considerable issues in terms of control over disperse manufacturers, introducing considerable supply chain risk of disruption into the process of meeting customer demand (Tse et al. 2016). The following literature review provides an overview of a selection of supply chain literature, giving particular attention on localisation. The most influential topic was the role of food supply and security, as supply chains became progressively more globalised. One of the most influential pieces was by Lang (1999), who posed a number of important questions related to the impact of the global food supply chain and global levels of nutrition. While focusing upon a dramatically different context to cricket bats, his insight shows how changes to supply chain design could influence global demand.

In addition to the benefits of global production, the context of the food supply chain also provided insight on the benefits of localisation food productions closer to the market. Atallah et al. (2014) and Rothwell et al. (2016) employed simulation based research techniques to explore the impact of localising local productions of vegetables (lettuce and broccoli respectively). Each found that localising vegetable production reduced costs to the end users and environmental impact of supply chains, although there were limitations associated with assumptions in how the systems needed to be modelled. Exploring the impact of localisation on a more complex supply chain context (dairy), Nicholson et al. (2011) identified issues when localising that can increase costs more than the reduction of transport reduces them. Due to the need to process aspects of the milk supply chain, if production and assembly activities were localised as well as raw material production, costs tended to increase.

Research exploring non-food supply chains provided additional insight for the context of cricket bat supply chains. Kouvelis and Tang (2012) identify some risks associated with this situation, in terms of variations in product quality and delivery uncertainties arising from disperse production locales, reflecting issues discussing in the supply chain risk literature (Tse et al. 2016). Although risks may be present, and transport distances may increase significantly in global supply chains, these supply chain can also benefit from being views form a localisation perspective. Usui et al. (2017) showed the need for a strategic orientation, with establishing the supply chain being only the first stage of building a globally competitive supply network. Through focused development, Usui et al. (2017) showed supply chains with localised suppliers could be established with the potential for future improvement in performance.

Interesting, within the localisation literature, performance was focused around sustainability, giving attention to social and environmental measures, reflecting the triple bottom line perspective on business performance (Elkington 1999). Jaeglar and Burlat
(2014) considered that the social impact of supply chain decisions also need including, so their impact on supply chain design could be understood. Koberg and Longoni (2019) found that firms could choose between open (selecting suppliers) or closed (developing suppliers) orientations to achieve their aims of sustainability. This short review of selected literature provides key factors for consideration within the cricket bat supply chain, with attention on both the benefits, costs and the need to support developing within localisation discussions. Unfortunately, the literature discussing issues of localisation focused upon specific contexts, in the form of nearshore or offshore localisation. In comparison to this, the cricket bat supply chain manufactures both locally (in England) and globally (in India, amongst other locations), providing a unique opportunity to determine how the different manufacturers compete under different constraints. This leads to the presentation of the research question that we will work towards addressing within the current research.

RQ: How do small scale, local manufacturers compete with large, global manufacturers within a global market context?

The following section provides a summary of the research methods that were employed within the research.

**Design/methodology/approach:**

The research takes a theory building, qualitative approach (Meredith 1998), with the case data taking the form of a multi case study (Yin 2009) situated within single market. While multiple firms contribute to the research, due to the interconnectedness of the firms within the sample, each case can be directly compared with the other companies, due to selling the same product to largely the same customer (high quality, English Willow Bats). To explore the relevance of localisation practices to the global supply chain, observational and interview data were collected from site visits, supported by secondary company and sport related websites from four UK based manufacturers and three India based manufacturers. The four British firms were selected due to their reputation, access and their distinct approach to manufacturing bats, which was considered to provide a broad selection of approaches to operating. The three India firms were also selected due to reputation and access, who fortunately also chose distinct approaches to operating and manufactured at different volumes, although this was not an a priori selection criteria. Within both groups of firms, both the largest Indian and English manufacturer were included, providing a rich selection of firms operating with the cricket bat manufacturing market.

Data was used to produce firm specific case studies that covered a range of aspects of the manufacturing process, relationships with suppliers and the role of craft skills. These were returned to each case company to verify their accuracy and ensure each company was happy with the information that was included, helping ensure internal validity (Yin 2009). The case reports with the other data sources were then used as the foundation for analysis, which included within and cross case analysis (Eisenhardt 1989), both within groups of firms (English or Indian) and across the two groups. The findings of the analysis were then considered against a triple bottom line framework (Elkington 1999), to explore the relative local or global focus firms give to different benefits realised through development and how localisation affects this. Table 1 provides a summary of the companies involved in the research and data collected from and on them.
Findings:
Across the 7 companies there was considerable variation in their approach to manufacturing, how they engaged with clients (both commercial and end user), how they marketed their products and even business models. This was considered a real strength of the research to develop broad and in depth understanding of multiple parties involved in the global cricket bat supply chain. For brevity, the following section reports on how the approaches of the different firms affected how they performed against the triple bottom line framework, rather than discussing within-case issues in detail. By using this framework and reflecting the attention of the literature on issues of sustainability to address the research questions, understanding can be developed of how each firm develops an advantage based on the aspects of the framework.

Economic:
The nature of the raw material supply chain placed a considerable constraint on each manufacturer, effectively determining how many and what grade of willow clefts they received, that determined how much bats could be sold for. Interestingly, due to the control the major supplier had over the raw material, they implemented some interesting policies that supported the maintenance of the smaller suppliers. Within the Indian companies, less was discussed about the access to willow, although the smaller firm did mention that access to the best willow clefts did limit further expansion. While this firm

commented that the quality of willow had reduced, all firms received a range of willow quality based on the overall population of willow that had been harvested in a given year. The role of the supplier within the industry was further highlighted by them not offering the larger contracts with reduced unit prices. While this did not provide the Indian firms with a price-based advantage, this policy did increase the value of the larger contracts to the suppliers.

As a result of this, each of the British manufacturers gave considerable attention to the maintenance and protection of the willow allocation, as without this, they stated they would not be able to operate. Even those with alternate sources were still heavily reliant on the major supplier, in terms of both volume and the quality of the willow. Following this constraint, the next issue was whether each company was able to sell the products they manufactured. For the larger manufacturers, primary approach to marketing was through the sponsorship of international players. For the most traditional Indian manufacturer, this appeared to be a considerable business expense, dedicating areas of manufacturing to the production of products for a single player. This also appeared to represent a significant part of the marketing budgets for the larger UK firm, who saw the promotion of their products and brand through sponsorship as a key way to sell more products. For the smaller UK firms, marketing took the form of sponsoring or supporting mid-level players, with the aim of establishing and developing the reputation of their products at a level of player likely to invest in top quality equipment. This form of marketing could also be combined with direct involvement with retailers, so that when retailers were approached, they would be able to discuss the benefits of particular products over others.

For the larger two Indian firms, they chose alternate avenues for selling what they manufactured. By manufacturing products that would be marketed under different brands, focus could be given to the manufacture of the best quality products, both bats and soft goods that could be sold without the need to invest in marketing. This situation was exemplified by the medium-sized Indian firm, who only marketed their own brand to the domestic market on a small scale. For the larger firm, who had a significant presence within the global market in their own right, had the expense of marketing their own products, that were in competition with their own bats, simply labelled differently. For the smaller UK brands, due to the limited availability of willow, combined with capacity limitation in some cases, there were limited opportunities to manufacture for other brands. Notwithstanding this, there were opportunities for the smaller, boutique brands to manufacture tailored, customer bats for professionals, who may be sponsored by brands without the capability to meet specific player requirements that sponsors could not deliver.

Addressing these issues provided each firm with means of manufacturing a sufficient number of products to sustain their business, so demonstrating economic sustainability. Interestingly, the retail prices of each bat (depending on the grade) was similar across the brands, suggesting that those companies supplying to retailers were likely to be selling products for a similar price. Those larger brands would then be required to purchase from a third party, maintain a margin before selling to a retailer. This would suggest that overseas manufacturers would need to offer a similar discount as the difference between manufacturing for direct sale and manufacturing for a retailer. While the benefits associated with manufacturing in India in terms of lower wages can be appreciated, the
nature and multiple tiers of the supply chain (to a degree) appeared to balance cost-based issues for the UK and Indian firms.

Social
For the Indian companies, a critical factor they (and the brands they were supplying for) had to consider was the nature of the production environment. While it was possible for the international brands to purchase low cost, high quality products from a number of overseas manufacturers, this created supply chain risks if the suppliers had poor working conditions. Through both open and closed supply chain structures, purchasers either selected suppliers with good worker conditions, or supported firms to develop them, respectively. For the two larger Indian firms, great attention was given to developing manufacturing processes and environments, in addition to giving attention to separate non-work areas for staff. While these resulted in a trade-off of increased costs, they stated this increased process efficiency, so offsetting some of the additional investment, but were a requirement of working with the international brands.

The smaller, more traditional Indian manufacturer provided a useful counterpoint to the other two. With attention given to making the best bats, accessories and other sporting equipment, the processes were primarily manual, apart from basic saws and sanding equipment, operating out of cramped working areas. While there was a stark difference between these manufacturers and the other Indian manufacturers, the owner stated that all workers were supported and had been working for the company for a number of years. Interestingly, maintaining these traditional ways of making bats was highlighted as important for the company, as further mechanisation or automation may improve aspect of the process, but may ultimately result in job losses. With attention on maintaining employment and supporting those workers who have been with the company a long time, this route for improvement was not being considered.

The British manufacturers had different issues to consider within their manufacturing facility, focusing primarily on managing costs. Within the context of UK manufacturing, there are a range of rules and regulations that ensure certain criteria are met and working conditions are at a satisfactory level. Due to the accessibility of the manufacturing facilities, there were more opportunities for facilities to be visited by potential customers and audited to confirm suitability of conditions. With these requirements set, for the two more traditional manufacturers (BS1 and BS2), attention was given to selecting premises that did not increase overheads, with processes that were able to deliver products at the necessary cost, quality and quantity. For the other two companies (BS3 and BL), the direct sales and scale allowed the technological small firm and the size of the largest UK firm, respectively, to invest in dedicated facilities with separate show rooms. In the technological small firm, they were also able to invest in an in-door cricketing area, to allow prospective customers to try a number of products or even hire the area to third parties, increasing their service offering.

An interesting additional factor for the British manufacturers was the availability of wood-based craft skills. While craft skills were also difficult to source in India, makers stated there were people with the necessary woodworking skills that could be trained. As a consequence, a further factor the British manufacturers have to consider was how to develop craft skills or overcome the need for them. Although overcoming the need for craft skills removed this constraint, in terms of access to labour, reducing the amount of craft
skills created an unintended consequence. With cricket bats representing traditional products, produced through traditional craft-based processes. From discussions with manufacturers and players about the different brands involved in the research, while some customers may focus upon branding, others value the process and skills of the manufacturer more. As a result, while attempting to remove time consuming and expensive processes through process improvements, maintaining keys activities represents an important competitive criterion that needed maintaining. Without this, while products could be marketed as English willow made in the England, they could not be marketed as being hand crafted.

Environmental
Apart from some fumes emanating from a bubbling pot in the corners of one of the Indian manufacturers, the issue of environmental impact was not covered explicitly within any of the interviews. Notwithstanding this, the impact of the global supply chain on the environment needs to be considered. While the size and volume of the products being moved is small compared to other industries (such as the automotive), there are also interesting factors to consider for the willow processed in India, due to the need for it to be transported to India and (in some cases) back to the UK. While other bat related material (e.g. handles) and soft goods raw material do not have to be imported from the UK, the movement of the willow did add costs (economic and environmental) to the Indian finished good. For the UK based manufacturers, these are costs they do not have to bare. In addition to transportation costs, UK manufacturers also had the opportunity to source their own Willow from other wood merchants, directly from growers in the UK or grow their own (BS2). This could be considered as a way of providing the UK manufacturers a means of bypassing the main supplier and controlling the quality of their primary raw material that the Indian manufacturers do not have available to them.

Discussions
The relative lack of literature exploring issues of localisation allows this research to open an interesting area of study, which is further emphasised by the unique nature of the cricket bat supply chain. In comparison to previous reviews, by focusing attention upon a specific supply chain does not attempt to present generalisable findings relevant across domains. However, this research allows more focused insight compared to previous work, specifically literature reviews, whose work tends to result in rather general frameworks (see Seuring and Müller 2008, and Koberg and Longoni 2019). The work also allows a direct comparison between overseas brands, manufacturers and suppliers, with those companies operating out of the UK. This highlights the benefits and drawbacks of both approaches to manufacturing that cricketing brands are able to choose between. The final novel aspects of the supply chain are that not only are all the firms operating in the same final market (English Willow Cricket Bats), they are also part of a single supply chain, using a single raw material and for the majority, a single supplier.

Overall, this investigation of cricket bat making within the UK and India identifies some interesting factors at play within a unique supply chain context. The use of the triple bottom-line to organise and summarise the analysis of the 7 case companies has been critical to more clearly understand the issues the firms experience and how they relate to one another. While there are issues and problems identified and documented about the triple bottom-line (see Norman and MacDonald 2004), it does give attention to social aspects of the process that are at times overlooked (Jaegler and Burlat 2014). By exploring
the operational contexts, at a detailed, operational level, it was possible to consider how changes in operational processes lead to improvements across a range of performance measures (Despeisse et al. 2012), including social. The comparison also allowed insight on how social benefits can be different depending on the context that is being explored.

To begin addressing the research question, the findings show the firms operating from within the UK are afforded two important advantages over their Indian competitors. Firstly, while contact with their raw material supplier needed to be carefully managed, they were able to develop direct relationships, and alternative sources of material. In comparison, although the contracts may be on a different scale, so representing more important customers for the supplier, the Indian companies appeared wholly reliant and dependant on a single supplier. They were also dependent on the condition of the wood, following storage and transport over the course of a number of months. In comparison the British companies were able to receive their products (if requested) in a rawer form (unseasoned or uncut) to condition how they saw fit. As this was wholly controlled by the suppliers, this created a risk for the Indian suppliers, that the condition and processes related to the raw material were more out of their control and it was difficult for them to be monitored (Kouvelis and Tang 2012).

**Conclusion:**
Although the work has been focused upon cricket bat manufacturing that represents a unique supply chain, due to a single source and almost single supplier of raw material, it has unearthed some interesting related findings. The single supply chain provides a useful foundation for the research with each company operating within the supply chain with broadly the same raw material cost (withstanding transport costs). By also producing largely the same products, while there are a wide range of sub markets for Cricket bats, each ‘grade’ of bat competes against similarly graded bats (the standard of the raw material determines that standard/price of the finished good). Within such situations, particularly within a retail environment, or indeed for major sports brands, those suppliers able to provide products at lower costs, provide opportunities for shops and brands to increase their own profit margins. This situation was what led to the off-shoring of manufacturing, when it was possible to procure similar quality products at less cost than to manufacturing them locally. In particular for the sports brand selling a wide range of products, cricket bat design and manufacturing may not be a priority, compared to overall profitability of a portfolio of sports goods.

With this consistent background, it is possible to clearly compare how the different firms’ approaches to manufacturing bats impact their competitive position and the benefits they realise from their choices. This leads to an ability to compare how the processes present within these different manufacturing facilities impact both the end product and how they are marketed. For those companies producing for another brand, processes and facilities had to be designed and improved to meet the requirements, and in some cases, be marketed, by global sporting brands. This involved investing in aspects of the manufacturing facility away from the production process, allowing the brands to partially offset their decision to offshore manufacturing away from wholly being focused upon cost savings. This was exemplified by the firm with the long-term relationship with a supplier, who worked with the supplier on product design and marketed the standard of their production facility. This example demonstrates how a closed supply chain structure can
facilitate improvements that meet the needs of international companies across a range of TBL measures (Koberg and Longoni 2019).

For the UK based manufacturers, instead of needing to promote particular types of manufacturing facilities and conditions, as they were “English Willow”, “made in Britain”, working conditions were assured. As a consequence of this, the facilities focused upon the processes that were taking place and the products that were being produced. While the majority of the large brands had off-shored production, the companies that remained still needed to overcome the factors that had led to the off-shoring, higher operating costs and skilled labour shortages. As a consequence, the primary aim of the UK manufacturers was to design and develop processes that helped them reduce cost, which was further supported by reduced transport costs (Atallah, Gómez, and Björkman 2014), allowing them to remain competitive. However, it may not be possible to localise the production of other cricket products, such as soft goods, reflecting Nicholson et al. (2011), unless production costs can be manage, localising production could increase costs. It was then necessary for each firm to be able to demonstrate how their products and also services offered differentiated them from other local and international products that were available.

The maintenance of craft-based, traditional, bat-making skills in the UK could thus be seen as an important social benefit, adding value to the manufacturing landscape of the UK, that could provide these firms with a competitive advantage that was valued by customers. Closeness to the end user also provides opportunities to engage service oriented and development activities, supporting a direct sales model that was already being utilised by one of the UK manufacturers. Overall, the initial exploration into the context of cricket bat manufacturing provides both hope for the future of the industry, but also opportunities for developing. These may include coordinating developing activities across small manufacturers, such as growing will, that drawing from Usui et al. (2017) could provide benefits in the longer term.

Abstract

Strategic management of global production networks (GPN) is getting increasingly complex and continuously more relevant for the long-term success of producing companies. Each plant in the GPN needs to accomplish goals coming from strategic management to stay competitive by adjusting their plant capabilities. In tactical management, production ramp-up processes are a great chance to be used for adjusting plant capabilities due to the high investment and cost determination character. This paper faces the possibility to integrate production ramp-up processes in the strategic management of GPN. The approach identifies relevant ramp-up dimensions and processes for an early strategy achievement.

Keywords: Global production networks, production ramp-up, production strategy

Introduction

Companies of various sizes and industries structure their production in the form of global production networks (GPN) (Vánca, 2016; Bhinge et al., 2015). These networks correlate with different strategy levels of a company (Holweg and Helo, 2014). In order to achieve the particular strategy levels, each plant meets its strategic goals by aligning its plant capabilities. These individual contributions form the basis of the global production strategy. (Friedli et al., 2014)

When planning production ramp-ups for the future configuration in GPN, this has to be aligned with the strategy of the company. Individual processes during production ramp-up influence the plant. While there are approaches that only focus on specific fields of a production ramp-up, there is a need to operationalize production ramp-ups in a GPN (Nyhuis and Wiendahl, 2010). Other approaches focus on the systematization of change processes for increased changeability of factory structures, but do not take into account
the network character and comprehensive ramp-up processes (Löffler, 2011). The need for further research in this field focusing on performance measurement in GPN was identified by Cheng et al. and can be matched with strategic implications (Cheng et al., 2015). These strategic implications correspond to the theory of an integrated manufacturing strategy decision-making structure proposed by (Olhager and Feldmann, 2018).

To tackle this lack in research and industry, the purpose of this approach is to identify processes during production ramp-up with strategic implications. In a first step, the strategy contents of a global production strategy are analysed. Furthermore, the importance of the individual strategy contents is specified using the established "Market Qualifier/Order Winner" method from (Hill, 1993). In addition, a creativity study analyses and selects relevant influencing factors for the interpretation of the global production strategy in a time horizon of five years (Linstone and Turoff, 1975). These are called key influencing factors and they are analysed in greater detail for their future development. In the second step, plant capabilities, or performance measures of a plant, based on the work of (Reuter et al., 2016) and (Hallgren and Olhager, 2009) are expanded in the present paper and contrasted with the strategy contents in order to work out the influence of individual plants on the global production strategy in the GPN. Furthermore, industry and project characteristics are used to extend the developed model. In the following step, a modular production ramp-up process is developed which correlates to the action plan for a time horizon of approximately one to two years. Here, individual processes are worked out which influence the long-term global production strategy and therefore require special attention.

The remainder of this paper is structured as follows. First, an overview of relevant literature in the field of research is given, which emphasizes the introduced research gap. Thereafter, the developed procedure for the flexible and scalable design of a production ramp-up in GPN is presented. Afterwards, this approach will be validated through case studies with experts from the German automotive supplier industry, which will show the relevance in practice. The paper concludes with a discussion and an outlook on further research.

**Related work**

In the course of this paper, the topics of ramp-up management in GPN, strategy layers in GPN, changeability in GPN and plant capabilities need to be analysed in greater detail.

The production ramp-up in GPN has already been discussed several times in the literature. Becker et al. address the strategic production ramp-up in production networks of the automotive industry. They provide a mixed integer programming model, which calculates the optimal curve of a production ramp-up at different locations in the network. This optimization is assigned to operational management and has few strategic implications. Nevertheless, the authors position the strategic ramp-up planning between the strategic network planning and the operative planning of the production ramp-up, whereby only a conceptual classification takes place. (Becker et al., 2017)

Fitzek's contribution also focuses on ramp-up management in networks. He analyses relevant influencing factors of the production ramp-up, their interaction and gives design recommendations for ramp-up organisations, communication and other particularities. Neither individual phases of the production ramp-up are analysed in detail nor are strategic aspects for a long-term design of the GPN taken into consideration. (Fitzek, 2006)

Fischer also discusses influencing factors of the production ramp-up at different locations without devoting himself to network effects. He conceives a methodology to
evaluate different site conditions in the preparation phase of production ramp-ups. This evaluation serves as a starting point for various recommendations for action to design a production ramp-up. For example, the flexibility of a factory and expansion possibilities on the shop floor are put in the foreground in order to react to changing framework conditions. Despite this, the author does not take plant capabilities into account. (Fischer, 2015)

With regard to the anchoring of different strategy levels in a GPN, Friedli et al. are regarded as a pioneer and state of the art. In their work, they describe the global production strategy, which consists of the production strategy and the network strategy. These form the foundation of strategic decisions in the GPN. However, their work does not focus on the possibility of integrating the production ramp-up and external influencing factors into the strategic management of GPN. (Friedli et al., 2014) Other works like (Olhager and Feldmann, 2018) focus on the distribution of manufacturing strategy decision-making in GPN. They differentiate between network and plant level and find out that there are three types of decision-making. It is centralised by the network level or integrated between plant and network level or decentralised by the plant. The integrated perspective can be related to the integration of a single plant production ramp-up into the strategic decision making which is one of the focuses of the present paper. Löffler focuses on change management processes and the integration into strategic management, but does not exclusively include ramp-up processes. The author develops a system that allows to integrate transformation processes into the permanent adaptation of factories. (Löffler, 2011)

In the context of changeability, there are numerous approaches on how to handle changeability on plant level. In their approach, Lanza and Moser deal with an uncertain environment, which has to be regarded as the initial starting point for the concept of changeability. The authors analyse uncertain environmental factors to calculate the optimal design of GPN. Thus, the optimal configuration of the plants in the GPN is considered in detail. No focus is placed on the transformation of individual plants regarding the aspect of changeability. (Lanza and Moser, 2014)

Other researches like e.g. Haag focuses on the identification of changeability drivers in GPN. In doing so, he focuses on early-evaluation activities for an early knowledge of the transformation needs of the future. However, he does not focus on how to deal with this change and how to prepare one's own company for the change. (Haag, 2012)

Further approaches take the combination of strategic decisions and an external analysis into account. Moser et al. regard changeability in GPN as an important success factor for the future strategic orientation. Here, they consider external influencing factors and the degree of changeability that a GPN should have in order to act at minimum cost. However, ramp-up processes are not considered in detail and only a focus is placed on cost aspects. (Moser et al., 2017)

In the area of plant capabilities, there are several approaches describing different dimensions of plant capabilities. The most common is the site capability approach of Friedli. He introduced the site capabilities Costs, Specification Quality, Conformance Quality, Delivery Speed, Delivery Reliability, Design Flexibility, Delivery Flexibility, Service and Sustainability. Nonetheless, an integration of relevant ramp-up processes to develop these plant capabilities is not considered. (Friedli et al., 2014)

In summary, there are many approaches which focus on selected areas of ramp-up, strategic layers, changeability and plant capabilities in GPN. However, none of these approaches combines all aspects, which is necessary for the strategic management of future competitive GPN.
Approach of integrating ramp-up into strategic management of GPN

A framework based on the aforementioned topics of ramp-up management, strategic network planning and plant capabilities is proposed. These topics combine important aspects for a sustainable management of GPN.

In the strategic alignment of GPN, the interaction of individual plants is of importance. It is substantial to find a way to quantify strategic contents of a company with the capabilities of plants (Mengel, 2017). These strategic contents must follow the external developments of a company and have to be designed accordingly (Gausemeier et al., 2018). A GPN also achieves a higher performance than the mere aggregation of the performance of individual locations (Shi and Gregory, 1998). Here, the plant capabilities serve to relate the network performance based on individual plants. In order to adapt these capabilities purposefully, ramp-up processes in short terms are used. Furthermore, depending on the external development of influencing factors and the firm's strategy, not all plant capabilities and therefore not all ramp-up processes are relevant. Accordingly, the paper proposes a three-step approach that supports the company in integrating ramp-up processes into GPN's strategic management (see Figure 1). First, the company's strategy and the relevant environment is analysed. Second, on plant level, capabilities are regarded and matched with the strategy level. Third, actions in form of ramp-up activities are chosen to flexibly react to strategic decisions.

Figure 1: Approach to integrate ramp-up into strategic management

In a first step, the strategy contents of the global production strategy are analysed. These contents are divided into the nine dimensions: price, specification accuracy,
product quality, delivery reliability, delivery quality, product range, design flexibility, order quantity flexibility, innovation and service. (Friedli et al., 2014) They particularize the areas of specialization a company can undergo. Furthermore, the importance of the individual strategy contents is specified using the established "Market Qualifier/Order Winner" method from (Hill, 1993). Where each strategy contents is weighted regarding its importance for the future strategy of the firm. Market Qualifier symbolize aspects which are necessary for a firm to be competitive in a business area. Order Winner symbolize the factor which is the reason for purchasing a product from a firm. Moreover, a SWOT (strengths, weaknesses, opportunities, threats) analysis is performed for the GPN to validate the identified strategy contents of the global production strategy (Wheelen and Hunger, 2011). In addition, a creativity study analyses and selects relevant influencing factors for the interpretation of the global production strategy in a time horizon of five years (Linstone and Turoff, 1975). These are called key influencing factors and they are analysed in greater detail for their future development. Possible relevant influencing factors are market development, labour cost, culture, fluctuation and so on. The assessment of these key influencing factors is done via the widely known approach of (Gausemeier et al., 2018).

The second step of the approach is dedicated to the measurement of the capability of production plants. These individual capabilities are matched with the strategy contents of the global production strategy in order to make the influence of individual locations on the overall strategy achievement tangible. The detailed matching of the plant capabilities can be found in Table 1 and is derived through industry input via different workshops between researches and industry experts, as well as through an extensive literature review of relevant areas.

![Table 1: Matching of Global Production Strategy and Plant Capability](image)

The product mix flexibility is now used as a describing example. Here, this capability has a connection to design flexibility, product range and specification accuracy. This influence stems from the fact that the product mix flexibility is very broadly diversified and thus influences diverse strategic content. The product mix naturally influences the product range, since the mix is a subset of the range. In addition, design flexibility is influenced, as each mix can also produce different designs. High specification accuracy also correlates with product mix flexibility, as a higher product mix enables a lower specification accuracy. Therefore, a negative influence is also possible here. It should be noted that the influence of the plant capabilities on the strategy contents of the global production strategy is only of a qualitative nature. The operationalization of the relationships is another core field in this area of research.
In the third and last step of the approach, the ramp-up process model is presented. This has a large number of processes that can occur during ramp-up. It supports the network manager in selecting elementary processes to build up identified strategic plant capabilities. In Figure 2 an exemplary process, the layout planning in the dimension factory planning is shown.

\[\text{Factory Planning} \quad \text{Layout Planning} \]

\[\begin{array}{ccc}
\text{Improvement of Volume} & \text{Improvement of Delivery} & \text{Improvement of On Time} \\
\text{Flexibility by X \%} & \text{Speed by X \%} & \text{Delivery by X \%} \\
\end{array}\]

**Figure 2: Exemplary Process of the Ramp-Up Process Model**

Based on an extensive literature analysis and several workshops with industry experts from the field of automotive industry, a process model for the production ramp-up in GPN was developed. This consists of seven elementary plant dimensions. These are Human Resources, Research & Development, Factory Planning, Production, Logistics, Procurement & Purchasing as well as Marketing & Sales. During the implementation of the approach, the relevant processes for flexible ramp-up planning and thus the development of plant capabilities are disclosed to the network manager. Each process in the ramp-up process model is detailed via the influence of the specific process to the plant capabilities. Specifically, the dimension “factory planning” is important for the strategic development of plant capabilities in GPN (Heinen et al., 2010). The degree plant capability improvement for each process is done via expert interviews and workshops. An intensive research and detailed planning of this process during a production ramp-up can help to easily follow strategic guidelines for the future of a plant. Thus, after completing the first two steps of the presented approach, a guideline of processes for ramp-up is delivered to the user for each dimension of the model, if relevant.

The application and usage of the framework helps strategic network managers to make valuable decisions in the management of GPN due to the holistic approach and widely applicable nature. It can be used as a guideline for the strategic management process and gives guidelines on how to integrate ramp-up into this topic.

**Exemplary application of scalable and flexible ramp-up in automotive industry**

The case study method according to (Yin, 2014) is suitable for the validation of an approach or a framework. Case studies are particularly suitable for answering and exploring explanatory questions. Since the focus is on supporting the strategic management in GPN, a qualitative case study is applied (Eisenhardt, 1989).

In a case study, at best several companies are interviewed in order to obtain the largest possible range of solutions. For well-founded results, however, the number of companies surveyed can also be kept low (Dyer and Wilkins, 1991). Therefore, eight workshops with automotive suppliers headquartered in Germany were conducted. All these suppliers operate their production in GPN.

The first step in the design of the case study was to get an insight into the GPN of the companies in order to understand and grasp the problems as well as the challenges of the industry. Accordingly, a team of two scientists conducted various workshops with the industry. At these workshops different functions of the respective companies were
The participants were ramp-up managers, global operational excellence managers as well as COOs and CEOs. This was helpful and needed to get a broad overview about the structure and the strategic guidelines of the GPN. Following (Eisenhardt, 1989), detailed minutes of the workshops were collected within 24 hours of each workshop, including workshop data, conclusions and overall impressions.

When aggregating the results from the workshops, many similarities were noticed. This speaks for the similar challenges currently faced by German automotive suppliers. In the following the aggregated results of the workshops are presented.

In the first step of the approach, the strategic contents of service, innovation, delivery reliability and order quantity were regarded as particularly relevant for the future design of GPN. These are seen as order winners.

Service and innovation are very important for the strategy, especially for technology leaders. This is largely due to the disruption caused by electro mobility. In addition, the degree of servitization is increasing, with more and more suppliers offering a product-service-bundle (Colledani et al., 2016). Delivery reliability is also very important as the competition in the supply industry becomes stronger. Therefore, the reliability of the own company needs to be high. The order quantity flexibility is also an order winner. The project business with Overall Equipment Manufacturers (OEMs) is increasingly decisive for success. In this context, suppliers are often faced with very different quantities by the OEMs and it must be possible to react flexibly to these.

A SWOT analysis was carried out to substantiate these important strategic contents. This filters the relevant internal and external influences for the future design of the GPN and the production strategy. The elements of the SWOT analysis were developed by the company experts through brainstorming.

In summary, the quintessence of the analysis is that in the area of strengths, versatile production resources and a high depth of added value characterize all participating companies. In the area of weaknesses, it came out that customers sometimes have very high requirements with regard to delivery times. These may be hard to fulfill. In addition, the fluctuation of qualified personnel is a weak point. Opportunities lie in the area of market development in emerging markets, which means that new sales markets can be supplied. Threats are seen in the areas of an intensified competitive situation and the increasing demand for services. Companies must first act on this increased demand with a high quality to maintain their image sustainably.

For an in-depth analysis of the identified strengths and weaknesses, an external analysis was carried out with each of the companies in the respective workshops. On this basis, various scenarios were developed for the companies. Commonalities in the external analysis lay in the area of the elementary important influencing factors, which will be described in detail. Of great importance were the influencing factors market development, project business and competitive intensity.

Market development is elementary for the future design of the GPN of companies, since e.g. the business of the conventional combustion engine is shrinking and this loss can be counteracted by growth, especially in electro mobility.

The project business correlates strongly with the order strategy of the OEMs. These determine the production pace of the suppliers and the future strategic orientation of the GPN. Projects on many different continents mean for the suppliers also locations on these continents due to the strict delivery time requirements.

The competitive intensity is reflected in the delivery time, but also in the necessity to focus on the core competencies of the suppliers. Due to an increased competitive intensity, unique selling points must be inevitably anchored in the production strategy.
After analyzing the external influencing factors and having clear the strategy for the next years, one has to focus a specific plant in the GPN to start the development. This is necessary to have a good first step regarding the fulfillment of the firm’s strategy. In this plant, there is a ramp-up process planned for the future in each considered company, which has to be used for an early strategy alignment.

In step two, the plant capabilities and did the linking of the relevant strategy contents from the workshops were focused. There, the five most relevant plant capabilities for the future in the supplier industry were identified. These are on time delivery, delivery speed, volume flexibility, innovation capability and service capability. Through the connection to the strategy contents, the identification was straightforward. The experts from industry emphasized the simple connection and valued it. It is an easy way to make a fuzzy strategy transparent on plant level in a GPN.

After the clarification of the important plant capabilities, the next step was dedicated to the strategically important ramp-up processes. In the individual workshops, the ramp-up process model was introduced and fundamentally explained. Through the clear allocation of influences of the individual processes to the plant capabilities, the need for action and the focus for the design of the ramp-up became transparent.

In particular, it became clear through the workshops that processes in the areas of factory planning and human resources are very important for the identified plant capabilities. The processes location check, location planning, building planning and realization as well as layout planning are located in the factory planning area. All these processes contribute strategic importance to the plant capabilities volume flexibility, delivery speed and on time delivery. By a concentrated consideration of this area, a decision support for the ramp-up process is delivered to the participating companies. Thus, they can focus their activities more specifically and adjust their efforts accordingly.

For an improvement of the plant capabilities innovation capability and service capability, the area human resource is particularly suitable. In this area the processes personnel requirement planning, personnel recruitment and personnel development are considered. These processes can be focused to the extent that creative employees are hired to strengthen innovations. Furthermore, an atmosphere or corporate culture can be created in the personnel development process to promote innovation. This also strengthens service capability, since new product service bundles, for example, can be developed and marketed through innovations.

Consequently, the approach serves as a valid tool to make the connection between the production strategy, plant capabilities and ramp-up processes clear. The approach was validated successfully within industry through several workshops.

**Discussion**
The overriding goal of this research was to identify relevant ramp-up processes that can contribute to the early achievement of strategic goals. In order to achieve this, an approach driven by literature, which links the mentioned topics and transfers them into a procedural model, was developed. The developed approach takes up standardized aspects from common literature. In addition, the missing link to operational ramp-up management is explained and introduced.

The developed approach is validated by a case study. The case study consists of eight workshops with different companies from the automotive supplier industry. Due to the manageable number of workshops, a deep insight into the industry of automotive suppliers is delivered. The case study demonstrates how the approach can be used to steer day-to-day business during a ramp-up and to coordinate efforts.
The exact influence of individual ramp-up processes on plant capabilities remains unclear and requires an in-depth analysis. Different KPIs can be used for the influence. It requires an operationalization of the plant capabilities and the ramp-up processes for this impact direction. In addition, limitations are seen in a workshop number of eight. Further workshops in this topic area, in order to obtain a well-founded database, are recommended. Other industries can also be considered, but comparability between companies must be ensured. The contribution of this research is that it helps to clarify the relationship between the design of a ramp-up process and the strategic implications of the respective decisions. Also, it helps to scale and adapt identified processes in order to react to external disturbances and future developments. In addition, companies that are in the need of adapting their production strategy are supported by this research as important processes in the cause of the adaption are clearly stated out. The achieved results make it clear to planners in ramp-up management that certain processes are important in order to force the strategic importance of the plant in the GPN at an early stage of time.

Abstract
This conceptual paper applies and extends the factory role model to provide a production network view on mergers and acquisitions. We map the production networks of an exemplary buyer and target company to explore the framework's potential implications for M&A. We find that a production network view is able to give useful guidance in post-merger integration, restructuring and divestment decisions. It also allows to highlight potential strategic gains for the global manufacturing activity of the post-merger company. Moreover, it mitigates the risk of trading off strategic manufacturing capabilities against purported cost-synergies and might therefore aid the long-term performance of manufacturers.

Keywords: Global Operations, International Manufacturing, Mergers and Acquisitions

Introduction
Mergers and acquisitions (M&A) have a profound impact on the production networks of multinational companies as well as the manufacturing industry as a whole. As data of the UN Conference on Trade and Development reveals, the value of realised cross-border M&A in manufacturing has surpassed the value of announced greenfield projects by nearly 84 billion US dollar (approx. 10%) between 2015 and 2017 (UNCTAD, 2018). As of now, the literature on production networks appears to not fully mirror the practical importance of M&A for manufacturing companies. Usually, the literature does not discuss whether changes to the network are due to greenfield projects or brownfield acquisitions (cf. Olhager et al., 2015). Instead, researchers appear to imply a greenfield approach. Overall, the topic of M&A is mostly neglected in operations management (Ferdows, 2018; Zhang et al., 2010). As a consequence, the production network perspective does not realise its full potential in influencing M&A decisions despite their major implications for manufacturing companies. In this paper, we suggest an application
of a core theory of production network management, the factory role model, and explore its implications for M&A in the manufacturing industry.

M&A allows companies to access new markets, join forces with or against their competitors, realise scale and scope economies and acquire new technologies and knowledge (Graebner et al., 2017). One of the dominant factors driving M&A activity is companies’ potential to leverage their value creation by capitalising on synergies existing between companies. To establish which value the target company in question has, M&A practitioners draw on discounted cash flow analyses and past M&A transactions. However, as Gupta and Gerchak (2002) note, corporate finance methods focus on valuing the target firm, without factoring in important production characteristics of the acquiring firm. Hence, Gupta and Gerchak show how production flexibility and market demand of the acquiring company affect operational synergies. In a similar vein, we argue that important cues for the strategic implications of M&A deals in the manufacturing industry can be obtained from analysing the overall structure of the production networks of the buyer and target firm.

Providing a practitioner roadmap to achieving synergies, the popular Harvard M&A Playbook by Christensen et al. (2011) suggests, companies can leverage their business by “extracting [elements] from an acquired company and plugg[ing them] into the [parent company]”. In the realm of manufacturing, these elements could also be factories or networks of factories. This notion gives rise to our first research question (RQ1): How can manufacturing companies identify merger targets whose production network strategically complements their own network?

The advice of plugging in resources from the target company into the parent company, also puts a question mark over the fate of the remainder of the target company. As Meyer and Estrin (2001) and Estrin and Meyer (2011) show, post-merger restructuring measures might, in extreme cases, lead to a complete abandonment of the target company’s resources and organisational structures. Post-merger divestures of so-called “non-core assets” are not uncommon (Capron et al., 2001) and might have positive implications for firm performance (Moschieri and Mair, 2008). This leads to our second research question (RQ2): Which parts of the post-merger manufacturing network could potentially be divested to realise cost-synergies and which cannot?

Literature and background on M&A
The collective term M&A encompasses both, the fusion of two previously separate companies to a new firm (“merger”), as well as the transfer of assets, such as factories or business units, between companies (“acquisition”) (cf. Ghauri and Buckley, 2003). Some argue, that about 97% of all M&As are acquisitions and only 3% are mergers (Peng, 2009). Yet, the terminological distinction between the two is fuzzy, also considering the variously termed deal structures that exist (e.g. Emott, 2011). As the main body of the literature, we will summarise both phenomena under the term M&A or ‘merger’.

The literature has identified various motivations for M&A. The underlying literature is multidisciplinary and different social science disciplines focus on different aspects of M&A performance. The three predominant disciplines in the M&A literature are strategic management, economics and corporate finance. Angwin (2007) identifies the latter to mainly focus on one-time gains, such as decreasing tax liabilities, reducing cost of capital, systematic risk, or improving companies’ share price. In turn, classical considerations of economics in M&A would include the often quoted economies of scale and scope (e.g. Given, 1996) or aspects relating to bargaining power. The strategic management field
belaboured various aspects driving M&A such as the access to technological capability (e.g. Sears and Hoetker, 2014) or limiting competition (e.g. Porter, 1985).

Factors like these are often grouped and framed as operational and financial synergies existing between the involved companies (cf. Trautwein, 1990). In theory, the estimated level of synergies determines the maximum premium that is paid, exceeding the market value of the acquired company. However, one robust finding of the M&A literature is that only a small number of M&As are able to realise the aspired synergies. For instance, in a sample of McKinsey & Co encompassing 160 mergers, 70% of companies fail to realise the expected revenue synergies and 40% are unable to deliver the previously estimated cost synergies (Christofferson et al., 2004). As regards shareholder wealth, others find that “three out of four acquisitions fail” and shareholders might be off worse than before the merger (Selden and Colvin, 2003).

Key to the concept of operational synergies is the existence of overlap. The figure below from Payne (1987) illustrates how overlap in the value chain of buyer and target firm engenders potential synergy in the respective activities of the firm. Various contributions flash out this notion. For instance, Houston et al. (2001) consider the geographical overlap of operations to drive potential for cost savings from consolidation and divesture of redundant structures and operations. Related to this, Capron et al. (2001) show how merging companies in the same industry (i.e. in a horizontal merger) can gain economies of scale by selling off, shutting down or reducing, that is, divesting, excess capacities.

**Figure 1: Potential synergy from overlapping firm activities (Payne, 1987)**

Consolidation efforts such as these are embedded in the overall efforts of companies’ post-merger integration (e.g. Graebner et al., 2017). Some authors, go as far as arguing that all value creation happens in this phase (Jemison and Haspeslagh, 1991). In line with this, a growing literature focusses on various aspects of post-merger integration of different firm activities (e.g. Homburg and Bucerius, 2005; Wijnhoven et al., 2006), restructuring and divestment (Capron et al., 2001; Estrin and Meyer, 2011; Vidal and Mitchell, 2015).

Consolidation measures such as these have a potentially profound impact on the operations in question, and manufacturing in particular. The literature suggests that a well-designed and managed production network can be a source of competitive advantage.
(e.g. Gulati et al., 2000; Miltenburg, 2009; Shi and Gregory, 1998). The ensuing question of how can cost-based synergies as discussed above be realised without endangering the competitive advantage derived from a company’s strategic manufacturing set-up remains unaddressed. As of now, no frameworks exist which guide companies in their decision on which elements of a manufacturing network are particularly valuable in a M&A and should be sought-after. Neither does the literature offer guidance on the divestment decision of which parts of the production network are of lesser strategic importance and can be divested to realise cost-synergies. This amounts to a gap in the literature which appears especially concerning considering the “mantra” of rapid post-merger action and the industries’ focus on the first 100 post-merger days (e.g. Angwin, 2004). This way, the strategic long-term contribution of manufacturing in the company might be threatened by financial short-termism.

**M&A and production networks – Insights and cues**

Generally, it appears that, despite the impact of M&A on production sites and their operations, the operations management literature has, by and large, left the topic unattended (Ferdows, 2018). Hence, the questions addressed above appear to remain, by and large, unanswered. The purpose of this paper is to address these questions from a production network perspective, drawing on the existing literature in global operations management. Only a handful of pioneer works exist that approach the topic of M&A from a productions and operations management perspective, notably Srai et al. (2010) and Zhang et al. (2010). Yet, the literature has addressed a range of directly and indirectly related topics from various perspectives (cf. Cheng et al., 2015). Firstly, we will review the two above mentioned contributions of operations management on the topic of M&A. Afterwards, we review core contributions to the literature on manufacturing networks, on which we draw to propose a conceptual framework to answer the questions above.

A framework that investigates the operational dimensions of M&A is presented by Srai et al. (2010). Based on case studies, the authors identify the different phases of industrial cross-border M&A and the operations activities associated with it. One of their foci lays on the integration activities necessary to unlock operational synergies. In this context, a key aspect the authors discuss is the notion of overlap of regions and products which might alter the post-merger integration and steps necessary for it. Their key contribution is a framework which elucidates how operations activities contribute to value creation (as measurable by free cash flows) in M&As. As regards production networks, their framework suggests that especially network access, e.g. to markets and know-how, and network efficiency would contribute to value creation. With regard to the factor of network efficiency, the authors expand that asset reduction can lead to decreased capital expenditure and therefore contribute to an increase in free cash flows. However, the previously discussed questions of which assets are strategically important in the production network and which are not, are not addressed specifically.

The work of Zhang et al. (2010) focusses on the post-merger integration phase and seeks to understand how manufacturing networks are integrated in M&A. Focussing on the aspect of network configuration, the authors investigate the key integration issues of networks following M&A activity. In the framing of the authors, the above developed questions concern the structural dimension of network configuration. The key integrative issues related to this dimension would be “geography presence and business scope” in M&As pursuing the objective of growth, and “capacity utilisation and economics of scale” for efficiency seeking M&As. Again, the main purpose of this contribution lays on the identification of key issues such as these, rather than guidance in solving them.
Even though not addressing M&A specifically, general guidance on the configuration and coordination of manufacturing networks is provided by the conceptual literature on global production networks (cf. Cheng et al., 2015). To capture the M&A context, the current production network models would need to be extended. We present an overview of frameworks prevalent in the literature before presenting our conceptual model in the next chapter.

Several frameworks have been developed that shed light on different aspects of designing and managing international manufacturing networks. The majority of them is concerned with classifying networks. For instance, the IfM Manufacturing Network Typology defines four different network types based on their linkage between factories and geographical expansion (Shi and Gregory, 1998). Similarly, the McKinsey Network Phenotype Model identifies five different network types on the basis of their realisation of economies of scope/scale and their importance of local adaption and transaction costs (Abele et al., 2008).

Other models delve deeper into the meso and micro perspectives of international production networks. Most recently, Ferdows et al. (2016) suggests a framework to delayer production networks into subnetworks, according to the complexity of the production processes in question and the level of standardisation. Taking into account the average competency of the plant subnetwork, strategic anomalies and lack of congruency between the subnetworks position and its competencies can be identified. A plant view is provided by Ferdows (1989) and elaborated on in Ferdows (1997). The original model assigns distinct roles to factories of one company according to their competence and location advantage. Plants with lower levels of competency would merely produce products, while higher level plants would be akin to centres of excellence. Resulting are six distinct factory roles – Off-shore, source, outpost, lead, server and contributor factories. The resulting typology was empirically validated by Vereecke and Van Dierdonck (2002) and has helped to engender a productive stream of research on manufacturing networks (e.g. Cheng et al., 2011; Feldmann and Olhager, 2013; Maritan et al., 2004).

**Conceptual Model**

We draw on the logic of the plant role model and extend it to explore some of its possible implications for M&A between manufacturing companies. This allows us to address our two research questions to which a plant-level perspective is best-suited. We map the factories of two hypothetical example companies and their production network in the matrix of the plant role model and make a further addition. As discussed, one of the core drivers in M&A is cost synergy based on reducing redundancies and eliminating overlap. Therefore, we add the factor of total factory cost to the mapping, that is, production cost plus overhead. This allows comparisons between the two other determinant factors of the model and cost, the added factor. To make differently sized factories comparable, a view of total cost per unit produced would suggest itself.

We visualise the resulting conceptual model below. The specific depiction chosen has been inspired by Vereecke and Van Dierdonck (2002) as can be seen from the layout. The factories of the acquiring (parent) company are depicted as circles. The factories of the target company (i.e. the bought or to be bought company) are depicted as squares. The size of the indicator is shown proportional to the (estimated) total production cost, similar to the visualisations in Ferdows et al. (2016).

The resulting model is able to capture horizontal M&A between companies at similar positions of the value chain in the same industry. As will become apparent in our discussion of the proposed model, a certain substitutability is assumed between specific
subsets of the mapped factories, due to their operational overlap. Hence, the mapped networks of the respective two companies are to be understood as production (sub-)networks producing comparable products. With view to the point about product and geographical overlap made by Srai et al. (2010), this means that we focus on the overlapping production geographies (more precisely, their location features) within networks with overlapping products. This way, we shed light on some of the integration (and restructuring) issues mentioned by Zhang et al. (2010) and discussed above.

Figure 2: Extended factory role model for manufacturing M&A assessment – Mapping Example

Mapping the two production networks of the buyer and target firm reveals several opportunities existing between the manufacturing activities of the two companies. In the following, we will discuss the different implications of the mapping presented above as regards production network extension, synergy and restructuring/divestment. Where appropriate, we will highlight individual features of the mapping graphically.

Firstly, the mapping reveals core plants in the manufacturing network of the target firms which provide the buying firm a location advantage which it previously did not possess. In the example depicted above, the buyer company could gain a unique advantage in locally available skills (see second column from the left). None of the buyers current factories appears to access this location advantage as yet. In general, columns without or with only small overlap between buyer and target firm provide potential for the buyer firm to add location advantages to its network configuration.

Secondly, potential for the buyer firm to reconfigure the strategic features of its production networks can be assessed. In the shown example, the buyer firm’s network appears unipolar by tendency, characterised by the existence of only one plant with a high strategic role. Acquiring the target firm depicted in the example would provide the company the opportunity of upgrade its network by taking over two plants with high strategic role. In the mapping, opportunities like these can be assessed based on row-wise comparison between the production networks of the two companies.

Thirdly, asymmetries between plant’s strategic role and their total production cost become apparent. As shown in the legend, the size of the markers is displayed proportional to the total production cost of the plant. In the example above, the column “market” shows one factory with medium strategic role level which appears to cause total production costs comparable to factories with high strategic level. The relation between factories’ total cost and their level of strategic role can serve as an important input for the post-merger integration and restructuring process. In an effort to deliver on the estimated cost-savings, managers are likely to consider factories with high operating costs for downsizing, divestment or shut-down before others. By tendency, factories with higher strategic roles are likely to cause greater expenses (cf. Ferdows, 2018) and might therefore be threatened in particular by post-merger ambitions to cut

---

26th EurOMA Conference Operations Adding Value to Society

---

6
costs. Prematurely closing a factory with high strategic role might impair the competitive edge the company derives from its manufacturing network. The mapping above obviates this risk by showing the relation between a factory’s cost and its strategic role in the network. As hinted above, this makes it is possible to spot cost-anomalies in the post-merger company, that is factories whose total production cost exceed the level of cost expectable based on their strategic level. This might flag factories that require managerial attention to identify potentially inefficient/wasteful practices. Should double structures exist (e.g. two firms of the same role) in case of a cost/role anomaly and no other managerial actions be preferable, the situation might call for a restructuring (compare, point five). Of course, the exact measure needed would depend on the detail context, including the ability of the more efficient factory to absorb the capacities of the less efficient factory, creating economies of scale. In case of an existing double structure, a divestment, e.g. by selling the factory, would not lead to a loss of strategic advantage, given that a factory of the same or similar role exists. However, a momentous decision like this would need to be based in a more fine-grain assessment of the existing options, industrial environment and market development. It has to be considered that the access to location advantages of different plants is not always substitutable. For instance, two factories whose predominant location advantage is market access might serve their purpose in two different regions (see highlighting No. 2 in the figure below). The figure below shows two examples for potential double structures.

![Highlighted potential double structures (Mapping example)](image)

Fourthly, the model above informs the decision between which factories economies of scale and scope can be realised to achieve cost-synergies without impairing the strategic set-up of the production network. This relates back to the point on operational overlap. If the production networks’ output is to remain stable but the number of sites is intended to be reduced to realise cost synergies the production of some factories needs to be integrated in others. Based on the presented model, it suggests itself to consider proceeding column-wise, integrating the production of factories with low strategic role into the production of factories with high strategic role, if possible. Restructuring this way creates potential for economies of scale from increased production volumes at the site and economies of scope from shared overhead costs, without threatening the strategic capability level of the network. Proceeding the other way around (integrating the production of higher strategic role plants into lower strategic role plants) might jeopardise the strategic edge gained from the high capability role factory, unless it can migrate to the new location as well. The latter appears to be a more costly option which is, in addition, also rendered less feasible by the relative immobility of key collar workers and engineers between regions of the world. The alternative to restructuring column-wise is restructuring cross-column. However, integrating the buyer and target firms’ factories...
cross-column-wise could lower a company's access to the location advantage otherwise accessed by the to be integrated factory.

Figure 4: Examples of column wise and cross-column integration (Mapping Example)

Fifthly, mapping production networks of buyer and target firm highlights risks of losing strategic capability by means of an intended divestment targeted at realising cost reductions. As discussed above, high cost factories are likely to be in the crosshair of post-merger cost reduction measures. The presented mapping suggests to consider their strategic contribution to the network as well. This sets the total costs of the factory in context. Divesting or shutting down a factory with unique role (e.g. by innovating best practices or conducting pilot runs) might impair the strategic capability of the manufacturing network as a whole. Though short-term cost cuttings could be realised this way, the post-merger is at risk to endanger its long-term manufacturing advantage.

Lastly, a similar logic applies to the location advantages of factories. Divesting or shutting down a factory which has a unique location advantage in the post-merger production network deprives it of a strategic feature of its configuration. In the mapping example above, discontinuing the operation of the target firm’s factory that accesses an advantage in skills would lead to such situation (second column from the left).

Discussion
We explored the implications of an extended plant role model for M&A in the manufacturing industry. This way, we addressed implications of M&A for global production networks, shedding light on our two research questions. Research question one inquired into the possibility of a production network perspective guiding the decision of companies on which acquired production network could complement theirs well. Question number two was concerned with the decision of which parts of the post-merger company can be divested to realise cost-synergies and which cannot. In particular, this paper suggests that the constellation of strategic roles and location advantages present in the production networks of the buyer and target firms should be key considerations when making investment, divestment and restructuring decisions in the manufacturing industry. The suggested production network view guides companies’ decision on how to upgrade the strategic capability of their networks and gain locational advantages. Furthermore, it also informs between which production networks divestment and restructuring based cost-synergies can be realised without loss of strategic capability or locational advantage.

Contribution to the Literature
We provide an application-oriented framework that serves three purposes as regards the literature. Firstly, we address the gap of research on M&A in the operations management literature. This way, we also shed light on previously unaddressed production network
related issues concerning operational synergies as discussed in the general M&A literature. In doing so, we follow up and elaborate on some of the key points made in the pioneer works that proposed operational perspectives on M&A.

Limitations
As this paper is based on conceptual thought, it does not yet feature an empirical dimension. Furthermore, by considering only the primary location advantage of companies’ factories, a simplification is made as factories might have several location advantages.

Conclusion and Managerial Implications
This paper has provided a production network view on M&A. For this, we drew on the factory role model and extended it. The presented conceptual thought has potential to aid strategic decisions of manufacturing companies engaging in M&A activity. It suggests which firm’s production networks bear potential for ameliorating the configuration of the buyer firm’s own network. It also bears implications for divestment and restructuring decisions aimed at realising cost-synergies. Mapping the production networks of the buyer and the target company as suggested might prevent the situation in which the long-term competitive advantage of a firm is traded off against short-term savings. Overall, taking into account a production network viewpoint on M&A has potential to render M&A of manufacturing companies more successful.

Manufacturing execution systems in international manufacturing networks: from plant- to network-level

Abstract

Manufacturing companies digitalize their manufacturing for various reasons. Those with multiple plants in an international manufacturing network (IMN) have to distinguish which digitalization steps they take on a plant-level and which ones they take on a network-level. They consider manufacturing execution systems (MESs) usually on the single plant-level. However, a recent study with manufacturing companies from the German-speaking area showed that companies with successful activities in the digitalization of manufacturing see MESs as a topic on network-level. Further research needs to deepen the understanding of the antecedents determining the applicability of MES implementations on a network-level of a certain IMN.

Keywords: international manufacturing networks, manufacturing execution systems, digitalization

Introduction

Digitalization of manufacturing is important for manufacturing companies to increase their performance (Dalenogare et al., 2018) and flexibility in manufacturing (Kagermann et al., 2013). Various technologies deepen the integration of the physical and digital or rather cyber dimension of manufacturing and create a smart factory (Chen et al., 2018). Among these technologies are, for example, the Internet of Things (IoT), big data and cloud-computing.

Manufacturing execution systems (MESs) also support digitalization of manufacturing (Cottyn et al., 2011). Moreover, they contribute “to the manufacturing related to improvement of cost, quality, flexibility, conformity and reliability” (das Neves et al., 2015, p. 449). An MES is an integrated and modular system that processes real-time information along an entire manufacturing process (Gerberich, 2011; Kletti, 2015). It “fills the gap between the ERP system and the automated systems on the plant floor” (das Neves et al., 2015, p. 453). According to the technical standard VDI 5600 (VDI e.V.,
2016) as well as further standards like ISA-95 (American National Standards Institute, 2010) or IEC 62264-3 (American National Standards Institute, 2016), a MES may perform the following tasks:

- Order management
- Detailed scheduling and process control
- Equipment management
- Materials Management
- Human resources management
- Data acquisition
- Performance analysis
- Quality management
- Information Management
- Energy Management

International manufacturing networks (IMNs) refer to intra-firm networks of two or more globally dispersed and coordinated factories under the full financial control of one company (Ferdows, 1997; Shi and Gregory, 1998; Colotla, Shi and Gregory, 2003; Rudberg and Olhager, 2003). Factories or plants are basic building blocks of IMNs, hence there are two levels of analysis: first, the plant-level perspective and second, the network-level perspective. To stay competitive, IMNs have to improve their network configuration and coordination continually (Colotla, 2003; Friedli, Mundt and Thomas, 2014; Cheng, Farooq and Johansen, 2015). For them, digitalization of manufacturing adds an additional lever for more efficiency to their manufacturing plants and hence to the entire IMN (Kang et al., 2016; Thoben, Wiesner and Wuest, 2017). As already mentioned, MES are one tool that supports these efforts (Kletti, 2007).

International standards ((American National Standards Institute, 2010, 2016; VDI e.V., 2016) and literature (Scholten, 2009; Helo et al., 2014) relate MES to the steering of manufacturing on plant-level. Figure 1 displays this approach. Scholten (2009, p. 99), for example, considers it “more logical to install the system locally”. There is vast literature about operative and strategic implementation of MESs with a specific focus on the single plant level (Saenz de Úgarte, Artiba and Pellerin, 2009; Scholten, 2009). However, Almada-Lobo (2015, p. 18) sees MES as pivotal “in the performance, quality and agility needed for the challenges created by globalized manufacturing business”. While Helo et al. (2014, p. 646) identify restrictions and note that Current MES solutions can operate the manufacturing process, but not for distributed manufacturing.”

Only little literature extends MES to the network-level of IMNs. Benninghaus (Benninghaus, 2019, p. 207) finds that all six case companies he examined “use MES to steer and coordinate manufacturing network operations”. Scholten (2009, p. 99) recognizes that “it can be advantageous to use ‘copies’ of the same MES at the various plants, instead of developing a separate system for each plant”. However, one could imagine an even wide range of different kind of MES implementations in an IMN spanning from completely different MES (even by different providers) at each plant to one central and harmonized system connecting all plants. The last one would potentially allow steering an IMN like one virtual plant. Gölzer et al. (2015, p. 192) state it in the following way: ” In order to assure effective utilization of resources, companies have to use scale and scope effects which require mobility of product and resources volumes in the network”.

2
Since literature about the kinds of MES implications in an IMN is scarce, we aim to answer the following research questions:

1. What importance do MESs have for the management of IMNs on plant and network level?
2. How can the implementation structure of MESs look like in IMNs?

Method
Our research adopts a mixed method approach in accordance with Johnson, Onwuegbuzie and Turner (2007).

A large-scale quantitative survey with more than 120 participants from manufacturing companies headquartered in the German-speaking area answers the first research question. It was conducted online between 26 February 2018 and 14 May 2018. We designed the questionnaire in collaboration with industry experts and other senior academics (Dillman, Smyth and Christian, 2014). We proposed the research scope of digitalization in IMNs to a consortium of representatives of ten manufacturing companies from the German-speaking area. In a workshop, both, the academics and industry exports discussed potential questions for the questionnaire. We later clustered and structured them for the final questionnaire. Depending on each specific question, the participants had to answer from a plant- or network perspective, which was clearly marked. The sample of the survey consists of companies from various industries for more generalizability (Jaworski and Kohli, 1993). In collaboration with industry experts and other senior academics we identified five successful practice companies from the sample. The term...
successful practice company relates to the five best performing companies with regard to digitalization of manufacturing within the survey sample. We based the criteria for success on variety and maturity of implemented digital technologies.

Qualitative case study research based on interviews and workshops with company experts answers the second research question (Yin, 2009). One in depth cases shows the possibilities of implementing a MES in an IMN. The explorative nature of the research justifies this approach, but limits generalizability (Yin, 2009). We choose the cases from the survey sample because the company showed a highly successful use of digital technologies in manufacturing. It is one of the successful practice companies. Moreover, the chosen case company uses MES in its IMN and has already used two different kinds of implementations on the network-level. Thus, it is an ideal example to compare these kinds of implementation with their advantages and disadvantages. We gathered the case data during an interview with executives from the company and a workshop with managers and experts from the company. Both, senior academics as well as industry experts from the consortium took part in the workshop and evaluated the strategy and implementation of digital technologies within the case company.

**Results**

The five manufacturing companies within the survey sample, which perform best regarding the digitalization of manufacturing, have a higher implementation level of MES in their plants than other companies (Figure 2). All of them use a MES whereas only 25% of the other companies use fully implemented MESs and further 16% have first MES implementations. MES is the only tool or technology used by all five successful practice companies fully implemented among others such as robotics or augmented reality. While 80% of the successful practice companies use MES in a global implementation across their plants, hence, on a network-level, only 19% of the other companies in the sample use it for cross-site data processing. In contrast to the other companies, the successful practices use MES primary for data acquisition, equipment management and performance analysis as well as information and order management (Figure 3). Moreover, they see information management tasks performed by MESs as key for their digitalization activities (Figure 3).

![What is your current status regarding MES?](image-url)

**Figure 2 – Current status of survey participants regarding MES implementation**
Within the five successful practice companies, we identified two types of strategic MES implementations on a network level. One completely central and one decentralized approach with a global template across the plants of the IMNs. Both have in common that they connect all plants. However, especially data governance within the network differs. The selected case company has used both approaches one after another.

</tbody>
</table>

The case company is a leading manufacturer of electrical motors and products based on them. Table 1 shows a short overview. It has more than 15,000 employees that generated a revenue of more than two billion Euro in 2018. The company has more than 20 manufacturing plants worldwide with internal value streams going across the plants. The company headquarters is in Germany. It started the digitalization of manufacturing in 2008 with a special focus on the connection of machines. Men, technology and organization form integral parts of its digitalization of manufacturing strategy.

The company harmonized single solutions with regard to digital manufacturing in its plants to one global digital twin. This digital twin guarantees a seamless data flow in manufacturing from customer order to delivery. At first, the company used a central MES with a central database for all plants. However, this approach had some shortcomings. Real-time data transfer from the Chinese plant was not possible due to the restrictions imposed by the Great Firewall. Hence, the central MES was not working correctly. Moreover, server updates had to be coordinated between all plants. As a result, the case company switched to a MES with a global template.

Today, all plants of the case company use the same MES template. It determines, for example, the data structure of data gathered in manufacturing and standard processes for manufacturing. However, each plant runs its own server for the MES. It is even possible to run the template from a virtual server at a cloud-computing provider. The company allows no local changes to the MES. The central IT-department deploys all updates via the global template to one plant after another.

When a physical product is transferred from one plant of the network to another, the most important data of this product in the digital twin is also transferred to the next plant. This allows, for example, quality gates in one plant based on data from another. Hence, the MES task quality management is performed on a network-level. Thereby the case company autonomously blocks non-quality parts from further process steps on machines. This is an additional measure since the company noticed that some parts, which have been tested as scrap, still find their way to the next plant in the value stream. Without the autonomous blocking of the machine, a scrap part would undergo further process steps and might end up at a customer. Hence, the case company saves money by removing the non-quality part from the production line and guaranteeing that it does not reach a customer.
### Discussion

Our research gives insights in the importance of MESs for IMNs. They fulfil a wide range of tasks on a plant level. Additionally, the survey and case study showed that successful companies with regard to the digitalization of manufacturing also use MES on a network-level. This is in contrast to most of the findings in literature.

The case company applied two kind of possible implementations of MESs in an IMN, centrally in the network and decentral but harmonized via a global template. Both offer advantages related to a global, virtual plant. Especially the central MES handles the IMN like one local plant, allowing, for example, short-term capacity balancing. However, it also has some shortcomings for the application of the case company. That is why the company switched after a careful evaluation to the global template approach, which is also described in a similar way by Scholten (2009, chap. 6). Thereby it can overcome the disadvantages of the central approach but keep the advantages like cross-plant quality gates.

![Success vs Others](image-url)
This raises the question whether there are certain antecedents determining the applicability of MES implementations on the network level of a certain IMN. The approach of the case company is particularly valuable for this company because of its cross-plant value streams with the need for cross-plant quality management. Other companies producing the same product in multiple plants might be in need for a cross-plant detailed scheduling. This is another MES task. It allows short-term capacity balancing not only between machines in a single plant but also across plants in an IMN.

Hence, further research is needed to understand which kinds of MES configuration makes sense for which kind of IMN.

Abstract
Coordination of International Manufacturing Networks (IMN) is connected to challenges, especially as there is a lack of comprehensive overview over interfaces on all levels of the network. The purpose of this paper is therefore to outline the critical interfaces within an IMN and explore how such interfaces can contribute to a more efficient management of the network. By establishing a definition of interfaces, a systematic literature review have been conducted, the findings are categorised into interplant-, external-, and intraplant interfaces. Concluding with a call for further research and the importance of core plants within interplant interfaces is highlighted.

Keywords: Global Production Networks, Core Plant, Coordination

Introduction
Managing International Manufacturing Networks (IMN) is associated with two main issues, configuration and coordination (Colotla et al., 2003; Shi and Gregory, 1998). Decisions related to the structure of the network falls under the configuration aspect, whereas coordination is related to infrastructural links between individual plants (Colotla et al., 2003) and affects the competitiveness of the entire network (Shi and Gregory, 1998; Srai and Gregory, 2008). The geographic dispersion of plants entail a need for interdependent coordination thus the view of the network must be expended beyond the individual plant (Cheng et al., 2016; Rudberg and Olhager, 2003; Shi and Gregory, 1998). In fact, production decisions regarding plants and networks are often made independently also when they in fact are interdependent (Colotla et al., 2003). Challenges of
coordinating plants within IMN has been outlined in previous research (e.g. Rudberg and
West, 2008) and emphasis has been on the complexity of network (Shi and Gregory,
1998). Thus, changes in one plant can have minor or major consequences for the entire
network, redistribution of responsibilities might be more or less necessary as both
structure of the network and roles of the plants can be affected. When changes occur, the
interfaces within the network require an analysis (Feldmann et al., 2013). Yet, analysing
the interfaces when the need arises may delay the response to change, especially as there
is a gap in research concerning a holistic view of existing interfaces as well as
identification of which interfaces are critical for managing the IMN. The lack of research
can be derived from the different concepts used such as coordination (e.g. Rudberg and
Olhager, 2003) and integration (e.g. Cheng et al., 2016), however, these definitions
cannot provide a comprehensive overlook over interfaces that surpasses the complexity
of an IMN. Studies have instead been performed regarding bounded interfaces.
Consequently, a complete overlook over the existing interfaces within a network have not
been defined in previous research. Therefore, the purpose of this paper is to outline the
critical interfaces within an IMN and explore how such interfaces can contribute to a more
efficient management of the network.

Frame of reference and key concepts for the literature review
The context of IMN is provided below as well as a definition of interfaces which is
derived from key concepts.

International manufacturing network
Synergising dispersed plants into networks can gain competitive advantage (Ferdows,
1997a), thus harnessing the advantages of globalisation, such as greater market share and
profit (Ferdows, 1997b). IMN is distinguished by a specialisation in knowledge transfer
where the knowledge is derived in a central point of the network and implemented locally
(Barlett and Ghoshal, 1998). The central point is also called a lead plant (Ferdows, 1997b)
or a mother plant (Vereecke and Van Dierdonck, 2002) here it is referred to as a core
plant although other terms are used interchangeably. The core plant’s knowledge and
capabilities are exploited and diffused throughout the network (Barlett and Ghoshal,
1998; Enright and Subramanian, 2007; Ferdows, 1997b) and implementation of
transferred knowledge occurs with a high degree of autonomy concerning the details
(Barlett and Ghoshal, 1998).

From a network perspective, core plant is the innovator, or the knowledge creator, as
it participates in the development of products, processes and technologies (Enright and
Subramanian, 2007), thus being a pinnacle of knowledge (Ferdows, 1997b). Furthermore,
the responsibility of production process development is connected to the core plant
(Enright and Subramanian, 2007) as well as driving continuous improvements (Simon
and Nährer, 2008). Besides from the core plant, other plants in the network have different
roles to play which in turn determines which capabilities are necessary for actualise the
particular role (Demeter et al. 2017). The ultimate goal for a plant is to achieve a higher
role (Ferdows, 1997b) which is possible when capabilities are utilised in an appropriate
manner, for instance by exploiting current best practise and applying it in novel areas
(Demeter et al., 2017).

Coordination insufficiencies such as functional separation, cultural differences, and
connection of strategy and operations can be avoided by having an integrated view of the
relationships with the partners in a network which involves both the company and the
network itself as well as external partners (Jaehne et al., 2009). Hence, the interfaces need
to be outlined and provide an understanding of the parties involved in order to enhance management on all levels of the IMN.

Definition of interfaces
The key concepts which are used for establishing a definition for interfaces are integration and coordination. However, in an IMN context few definitions apply and are not defined in a uniform manner. Firstly, the term integration is examined in the next paragraph regarding its attributes and the IMN levels involved. Secondly, coordination is analysed in the same manner. Table 1 presents key attributes of integration and coordination as well as the IMN level they apply in the examined literature.

The concept of integration is classified as two types according to Cheng and Farooq (2018) and Cheng et al. (2016), which is external and internal where both involve collaboration and synchronisation of activities, whether that is between a plant and their external partners or within its own organisations. Similarly, O’Leary-Kelly and Flores (2002) define integration working together in a cooperative manner, which applies also to parties that are separated. Moreover, integration is used in a network level, Golini et al. (2016) define both interaction and collaboration as attributes in integration, the difference being that in the network perspective the goal is to achieve results together by utilising more than one plant. Hence, integration definitions occur at different levels of the network which is at occasions unclear. For instance, Vandeveld et al. (2002) defines integration as collaboration and exchange of information, but Kahn (1996) emphasises collaboration due to insufficiency of solely information exchange. Lawrence and Lorsch (1967) describes integration simply as the process to achieve unity of subsystems.

</tbody>
</table>

The concept of coordination is subjected to similar lack of uniformity. From a network perspective, Cheng et al. (2016) and Cheng and Farooq (2018) define interplant coordination as a link or integration with other plants within the network while Holm et al. (2005) and Kawai and Strange (2014) uses the term embeddedness that involves both
external and interplant collaboration, latter being on the network level. In contrast, Fleury et al. (2015) state that coordination includes linking or integrating production and distribution. Furthermore, Gammelgaard et al. (2012) emphasises that autonomy in itself is an important mechanism of coordination which McDonald et al. (2008) state allows plant managers to make strategical and operational decisions. Overall, Rudberg and Olhager (2003) explain that complex networks might settle for synchronisation or harmonisation rather than coordination.

Both coordination and integration are relevant in order to coin a definition for interfaces in the IMN context, however, the existing terminology is contradicting concerning which term should be applied on what level of the IMN and between what entities as exemplified above. Therefore, interfaces in IMN are defined as associated links between internal organisations, plants within the network and with external partners to enable an efficient coordination and integration (Cheng et al., 2016; Cheng and Farooq, 2018; Golini et al., 2016; Vandevelde et al., 2002). Thus, all possible boundaries that exist in an IMN are included. The interface definition can thereby provide uniformity as well as combining the important attributes in both integration and coordination which is not possible if the terms are used standalone in the IMN context.

Research design
Within IMN and the core plant context, the term interface is not commonly utilised, thus a definition of the term within the context was performed as seen in the previous section. The approach to examine definitions of existing terminology and introduce a term from another research fields provided a novel viewpoint to examine existing research within IMN. The procedure for conducting a systematic literature review was inspired by Frishammar et al. (2012) making the initial step scanning to identify existing literature within IMN, starting with a read through of frequently cited articles and dissertations in order to establish most relevant keywords. The keywords were derived from the established definition of interface and the adjacent terms that the definition contains (e.g. collaboration, link, integration etc.). Additionally, the field of core plant and the most commonly used terminology, such as master plant and lead plant, was combined along with interface, as well as with IMN. The formal search for literature was conducted in three main databases, Emerald Insight, ABI/INFORM Global and Scopus. Additional articles were found by the snowball technique and by using key literature such as Shi and Gregory (1998) and Cheng et al. (2016).

Selection of articles were limited to peer-reviewed, and written mostly from an operations management point of view, although relevant input from other disciplines have been included. Fields of product development, supply chain management, international business management, and organisational management were also scanned to provide a holistic view of the existing interfaces within an IMN, meaning that a network perspective was utilised along with a plant perspective. Articles were excluded when a correlation with interfaces were lacking or were outside of the scope of this paper, i.e. literature solely from a headquarters perspective. Totally, 27 papers were selected for analysis where firstly the abstracts and conclusions were scanned and secondly the papers were read and analysed in full. The analysis was conducted systematically by construction of a table with categories for interfaces, this was performed in two steps. Firstly, the categories were; bibliographical information, terminology correlated with interfaces, focus (whether what, where or how was answered), main findings, perspective (plant, network, external or combined) and lastly consequences for the IMN. From this categorisation new categories emerged concerning the existing interfaces, that is; intraplant, interplant and external. This categorisation intended to separate interfaces depending on the levels of
IMN where they are occurring. Accordingly a rearrangement was necessary where the different types of interfaces were on one axis and the head categories on the other axis which could be derived either to what the interfaces contribute with to the network and how they are arranged or actualised. Both what and how categories had individual sub-categories.

**Results: Critical interfaces for managing international manufacturing networks**

The literature analysis found three categories of critical interfaces in IMN, namely, intraplant-, interplant-, and external interfaces. The following section explain each category of interfaces in detail.

**Intraplant interfaces**

Intraplant interfaces are expressed through the structure of intra-organisational practices, procedures and behaviours which are supposed to be synchronised and collaborative processes across functions within a plant (Schoenherr and Swink, 2012). The effects of the interfaces are facilitation of information sharing across functions which can enhance strategic cooperation (Wong et al., 2011) as it breaks down functional barriers (Cheng et al., 2016). Examples of intraplant interfaces are between function such as purchasing and sales as well as both functions interfaces with production concerning joint decisions making and information sharing (Cheng and Farooq, 2018).

Intraplant interfaces are an enabler for external interfaces, meaning, for enhancing the latter as well as the overall operational performance, the plant could firstly improve the intraplant interfaces. However, the precondition of cooperation with external partners must also be fulfilled as close cooperation with external partners is an enabler (Cheng et al., 2016) that provides a learning opportunity (Lane et al., 2006). Similarly, well developed intraplant interfaces where the functions are able to learn from other plants in the network can enable interplant interfaces (Cheng et al., 2016). This relation between intra- and interplant interfaces also affect allocation of production and distribution among plant (Rudberg and Olhager, 2003). This is supported by Vereecke et al. (2006) who connects higher capabilities in a plant with frequent interaction with the rest of the network, making the plant a true player. Thus, Olhager et al. (2015) point out that intraplant interfaces between internal functions are viewed as important. However, all abovementioned is not feasible if the plant lacks well-established internal systems and capabilities necessary to share information on plant level, meaning there will be a lag when information becomes available within the interplant interfaces (Cheng et al., 2016).

**Interplant interfaces**

Interfaces between plants within IMN, and in which manner they are set up, are here defined as interplant interfaces. These interfaces are considered both from plant and network level and how a plant is supposed to integrate (Cheng et al., 2015a) and collaborate with the rest of the IMN in order to reach the strategic objective of the company (Cheng et al., 2016). Coordination of production capacity can for instance improve delivery performance (Cheng et al., 2016; Flaherty, 1996). Furthermore, exchanging production experience, knowledge and innovation, can reduce product cost and improve product quality as plants in the network can improve process and product design by gaining knowledge, resources and capabilities from other plants instead of developing them separately at individual plants (Cheng et al., 2016). Moreover, by transferring production processes from the core plant to other plants within the network, performance consistency can be reached in the network thus creating synergy (Lu et al., 2010). If the plants within the network can develop and achieve high performance without
the contribution of the core plant, a network reconfiguration can be triggered (Lang et al., 2014). When reconfiguration and change occur and new responsibilities are added to one plant, new interfaces are created in the network while also affecting the plant that previously hosted the activities and therefore may need to reduce its competence accordingly. Thus, changing roles has an effect on the network structure as well as on the roles of other plants, making the change a concern for the entire network which must adapt to new circumstances (Feldmann et al., 2013).

It is expected that the core plant coordinates activities across the interplant interfaces (Maritan et al., 2004; Tran et al., 2010), as well as interfaces to external partners (Tran et al., 2010) which can restrict the freedom the core plant has over making independent decisions for its own operations (Cheng and Farooq, 2018; Maritan et al., 2004). The core plant has for instance the same amount of autonomy over planning decisions as other plants in the network (Maritan et al., 2004). The lack of autonomy can be derived from overload of received information from the mentioned interfaces (Tran et al., 2010).

A manner in which the interplant interfaces can be organised are presented by Rudberg and West (2008) where network-based competence groups are assembled from specialists in different plants. This taskforce ensures that the knowledge is kept global instead of local by establishing a structure. The responsibility of updating the core plant on the happenings on plant level as well as transferring the information throughout the network is allocated to this groups, in other words, a platform for communication is established which eliminates the need for central functions. This sort of interface can be linked to Martinez and Jarillo's (1989) informal coordination, which involves communication within plants, training and development programs and transfer of managers. According to Ferdows (1997b), interplant interfaces are expressed as the core plant is a partner to headquarters regarding developing strategic capabilities in production. But also by continuously communicating with centres of knowledge, customers, machinery suppliers and research laboratories. Moreover, Cheng et al. (2015b) propose that an interplant interface exist between production and R&D.

Belonging to an IMN, thus having interplant interfaces where knowledge can be transferred between the individual plants, can have a positive effect on the external interfaces, in this case with suppliers. Collaborative relationships within external interfaces can thereby be developed that leads to better overall performance (Golini et al., 2016). However, external interfaces, specifically concerning customers, can have a negative effect on interplant interfaces (Cheng et al., 2016) regarding product and production transfer between plants as local adaptations must occur in order to reach an appropriate fit with the local market (Cheng et al., 2015b).

**External interfaces**

The definition of external interfaces is the extent of a plant’s collaboration, coordination and information sharing with its external partners. In fact, according to Zhao et al. (2011) the outcome of these interfaces are collaborative and synchronized processes and systems which can be achieved through structure of a plants inter-organisational strategies, practices, procedures and behaviours with its external partners. However, Cheng et al. (2016) point out that external interfaces are seldom investigated beyond the plant level collaboration across internal functions with suppliers and customers. Feldmann and Olhager (2013) remark that increased or added responsibilities regarding supply chain activities can besides from strengthen current activities at the plant, provide a higher degree of control over production. On the other hand, according to Camuffo et al. (2007) close collaboration with suppliers is a necessity in production relocation within the network. Furthermore, Feldmann et al. (2013) state that increasing capabilities in one site
where supply chain responsibility is assigned must also expand its supply network to match its added operations, leading to a lower need for frequent inter-continental coordination. However, some interface still remain unaffected as product and process development is confined to the core plant.

External interfaces are actualised through coordination and information sharing with key suppliers to enable effective planning and forecasting, product and process design, and transaction management. On plant level, the benefits are of receiving an insight into the suppliers processes, capabilities and also constraints (Ragatz et al., 2002). By extending the interfaces to key customers through close collaboration and information sharing, the outcome can be of insight into market expectations and opportunities (Wong et al., 2011) as well as understanding of customer preferences and development of relationships (Swink et al., 2007) and improving operational performance also for a plant belonging to a IMN. The components for external interfaces are extending to joint decision making and system coupling with key suppliers and customers (Cheng et al., 2016) and synchronised processes (Chen and Paulraj, 2004; Zhao et al., 2011). For a plant within a network, the synchronisation of operations with suppliers and sub-suppliers can enhance the material flow in the sense of speed and evenness, thereby providing cost efficiency (Shah and Ward, 2007). From a supplier point of view the gains are of the ability to anticipate and understand the plant’s needs which in turn benefits the plant with on time production as well as resolving conflicting objectives (Cheng et al., 2016).

In summary, how the interfaces can affect efficient management of the IMN is presented in Table 2.

Discussion
This paper contributes with outlining the critical interfaces within an IMN and explored how such interfaces contribute to a more efficient management of the network by using a systematic literature review approach. The critical interfaces are identified in three
categories; intraplant, interplant and external interfaces. However, intraplant interfaces are found to be correlated with other defined interfaces in an IMN, and is therefore classified as an enabler for the rest of the interfaces. Colotla et al. (2003) state that production decisions in the network are interdependent, this paper confirms that interfaces cannot be viewed as standalone entities. Rather, they affect, enable or support each other.

Intraplant interfaces are actualised by the structure of intra-organisational practices, procedures and behaviours (Schoenherr and Swink, 2012). For instance between functions such as purchasing, sales and production as these functions are dependent upon each other’s information in order to make joint decisions (Cheng and Farooq, 2018). By taking advantage of the opportunity to learn within external interfaces, the intraplant interfaces can be enhanced which can improve interplant interfaces as well. A precondition is however that well-established internal systems are in place, as well as capabilities necessary to share information on plant level (Cheng et al., 2016).

The external interfaces can be actualised through joint decision making (Cheng et al., 2016) and synchronised processes with both key suppliers and customer (Chen and Paulraj, 2004; Zhao et al., 2011). When adding on supply chain responsibilities to a plant, new interfaces can arise in the network which can lower the need of coordination. However, other interfaces, which are typically the core plant responsibility, are not affected. An example of the unaffected interfaces are with product and production development. At the same time the plant which gained the supply chain responsibility has increased control over production (Feldmann et al., 2013). Thus, a network reconfiguration can be triggered (Lang et al., 2014). Hence, the external interfaces can be a trigger which affects other interfaces, creates new ones, and can lead to reconfiguration of the network.

Another major finding is that interplant interfaces are correlated with the core plant responsibilities. Coordination of activities are performed by the core plant as Tran et al. (2010) and Maritan et al. (2004) point out, thus the activities are the manner in which the interplant interfaces are actualised. Cheng et al. (2016) also adds that exchanging of production experience, knowledge and innovation can lead to a more efficient network as plants can benefit from each other and save resources needed to develop these individually, additionally, synergy of the network can be created. A relevant study by Rudberg and West (2008) present a solution for how intraplant interfaces are structured in practice consisting of network based competence groups that updates the core plant and transfers information in the network, thereby keeps the knowledge global and within the network rather than local within the intraplant interfaces. Martinez and Jarillo (1989) write about informal coordination which links to the aforementioned empirical study and Ferdows (1997b) mentions development of strategic capabilities and communication with relevant entities where interfaces are actualised, also bringing the core plant forward within interplant interfaces. The interfaces are between the core plant and headquarters and machinery suppliers among others. A core plant is therefore here classified as both the enabler of the interfaces and a facilitator for coordination within them.

Conclusion and future work
Several findings have been presented in this paper, the foremost important being that interfaces on all levels of the IMN affect, enable and facilitate one another. Additionally, the core plant have been identified as an enabler and a facilitator for interplant interfaces which has great significance regarding how the IMN could be coordinated. However, the latter finding needs more research, preferably by using the categorisation of interfaces coined here. One of the analysis categories for this paper was how the interfaces are actually realised. Generally, there is a lack of research focusing on categorisation or
identification of present interfaces within the IMN context, or more importantly, an explanation which pinpoints how the interfaces are constructed and organised is seldom presented. Hence, deep-probing research is necessary to fully understand how interfaces are actualised and outline them in greater detail, the necessity of empirical studies is thus recognised. This paper presents a categorisation and a starting point for future research where a continuation could be to establish how interfaces on different levels of the IMN affect the strategical objectives of the company. Moreover, an examination of how the interfaces can be streamlined in order to achieve such objectives by utilising the core plant as a facilitator given the plants role would be an important contribution of future work.

Abstract

A wide literature about International Manufacturing Networks (IMNs) has been developed in the last decades, driven by the globalization of operations. Attention has typically been directed on plant and network level, while little emphasis was given to subgroups of plants within the same company. This paper aims at providing a definition of the “subnetwork” concept, as introduced by Ferdows et al. (2016). The research highlights the main characteristics of subnetworks, and the reasons why a subnetwork-based analysis can be useful for providing additional insights over three core topics of IMNs: the role of the plants, capabilities, and manufacturing strategy.

Keywords: International Manufacturing Networks, Manufacturing Subnetworks Definition

1. Introduction

The globalization of companies has forced managers to develop new organizational approaches due the internationalization of operations and the expansion of production, purchasing and distribution from a single nation to a global scale (Meijboom and Voordijk, 2003). In an attempt to analyze the complexity of the phenomena behind the globalization of companies, over the years a rich literature has developed with specific focus to the International Manufacturing Networks (IMNs), where attention has gradually shifted from the individual plant within the supply chain, to a network of plants mutually connected and mutually dependent (Rudberg and Olhager, 2003a).

IMNs can be studied from different perspectives depending on the level of specificity of the analysis: by considering the individual plants, groups of plants, or the entire network. Despite the borderline between the analysis of a single plant and analysis of the entire network has gradually narrowed (Cheng et al., 2015), the literature has mainly
considered only these two levels of detail. In this work we will focus on the concept of "subnetwork", as first elaborated by Ferdows et al. (2016). They suggested to divide a complex organization into smaller and more congruent parts in their production mission; they explained the subnetwork as the set of multiple plants "on the basis of complexity and proprietary information in the products they produce and production processes they use to produce them". Other authors (Golini et al., 2017) have supported the research about subnetworks, providing some further evidence.

The understanding of subnetworks in international companies is however far from being completed. In particular, a theoretical conceptualization of the underlying elements of subnetworks still need to be developed; in addition, companies and researchers lack the necessary awareness of the concept and how it can be useful in understanding operations management. Thus, the research questions we want to address in this paper are basically two.

First: What is a subnetwork? A subnetwork is still not a clearly defined object, and it still lacks well-defined boundaries. To our knowledge, there is an extremely weak empirical evidence that can allow us to give a univocal definition. The study of subnetworks in IMNs is still characterized by a lack of consensus on a precise definition and this issue needs to be addressed. This risks to hinder clearness: the use of the concept of subnetworks risks to be used in an inappropriate way: the term “subnetwork” is sometimes used to express diverse concepts such as network and business unit, or it is often used to indicate other criteria for grouping activities in manufacturing companies. In this paper, thus, we aim at providing a clear definition of this concept and a clear understating of its difference compared to other commonly used elements.

Second: how can the concept of subnetwork help in the analysis and comprehension of manufacturing networks? Once that the characteristics of subnetworks have been recognized and a coherent definition has been provided, the paper wants to show why and in which cases an approach based on manufacturing subnetworks can provide beneficial insights for the company’s management. In other words, it is not clear what is the practical relevance of subnetwork classification criteria and why could companies benefit from using subnetworks.

2. Literature background
Subnetwork approach can be included in the wider theme of International Manufacturing Networks (IMN).

In general, IMN literature can be divided into two main streams: i) the role of a plant within a defined network and ii) the network structure (Cheng et al., 2015). Shi et al. (1997) and Shi and Gregory (1998) were among the first to try to understand the structural characteristics of international manufacturing plants; they also explained how every node (every plant) in an IMN is connected and affects the behavior of other plants and cannot be managed in isolation. A similar and more recent result comes from (Cheng et al., 2011a). Besides, a special attention was dedicated to IMN categorization: there have been various attempts to model and categorize international or global companies, taking the entire network as the unit of analysis. Depending on the drivers considered, different models were developed to explain and manage the structure of IMNs (Bartlett and Ghosal, 1998, Shi and Gregory, 1998; Hayes et al., 2005; Rudberg and Olhager, 2003b). Within the literature about the network structure, a further distinction can be made between the analysis of network configuration and the analysis of network coordination. These two strands concentrate much of the global network literature (Feldmann et al., 2009). The first concerns the "where", i.e. the location of plants and activities typically involved in the value chain, i.e. it concerns itself with the structure (nodes) of the network (Meijboom
The second deals with the infrastructure, i.e. the relational aspects and organizational processes between different plants (connections between nodes) (Colotla et al., 2003).

Close to our research, the input about subnetworks has its origins in a series of works by Ferdows (1997, 2008), through which the author, in line with what was anticipated by Skinner (1974), explains the need to simplify an international production network. Ferdows (2009) proposed a framework to guide the evolution of production networks and to guide strategic choices. In particular, he clarifies two opposite models of network management: the first model explains how to create a "footloose" network, i.e. a network that frequently moves manufacturing activities to find the best location in that time context; the other model explains how to develop "rooted" networks, i.e. networks with plants that are stable in space and time and that, despite they do not benefit from low-cost countries advantages, can maintain high-quality standard by means of a higher level of competences and know-how.

A basic point that has recently been outlined (Ferdows et al., 2016) is that the same logic of rooted and footloose network can also be applied to groups of plants within the same network and not necessarily to the entire network. Ferdows proposes that the simplification of the network should be applied to a "group of factories", that somehow work together to complete the business goal. The final objective is to reduce the complexity of the network by breaking it down into simpler and easier to manage "subnetworks". This ambitious goal was supported by the increasing complexity of the today’s large organization and the set of internal and external factors that affect IMNs, which makes it complex to verify the performance and mission of the network when considered in its entirety. Ferdows’ provides a matrix (with complexity/proprietary information level of products and processes on the two axes) to represent four typical types of subnetworks: besides rooted and footloose subnetworks, two intermediate and less frequent situations are depicted: “Process innovation network”, with simple or standardized products but complex or proprietary process, and on the other side, “Low investment networks”, characterized by simple or standard process but complex or proprietary products. Ferdows’ matrix can be the starting point for a series of interpretation and analysis on IMNs. Moreover, just as the single plants must be "focused", and concentrate only a limited number of manufacturing missions at the same time (Skinner, 1974), the subnetworks must also be focused and built in such a way as to respond correctly to their mission (Ferdows et al., 2016). The skills developed and the know-how brought in must be suitable for the strategy adopted. It will be possible to focus on every single subnetwork, thus simplifying the design and management of the entire network. When the subnetwork has adequate production objectives and the factories that make it up have the necessary skills to achieve them, this subnetwork is called "congruent" (Ferdows et al., 2016). Golini et al., 2017, in line with Ferdows' preliminary work, shifts the focus especially to the product, defining subnetworks as "sets of plants that produce products or finished goods with common characteristics".

3. What is a subnetwork?
The interpretation and the analysis of what is found in the literature suggest that many different themes have strong relations with subnetworks. In this section, the contents of the above literature review are discussed and used together with related themes, in order to derive a definition of “subnetwork”. Specifically, five elements are considered:

A) Basic structure: the subnetwork is identifiable through a concrete set of assets. These assets can be assigned to one subnetwork or another both exclusively and simultaneously: if a plant includes more than one production line, with different products
realized and processes used, the same plant can be assigned to more than one subnetwork. It means that in subnetwork identification, a partial overlapping can exist. Vice versa, different plants can be dedicated to different product groups and so they belong to independent subnetworks.

B) Subnetworks classification criteria: what really differentiates subnetworks from other differentiating criteria, is the fact that multiple dimensions have to be considered. Ferdows’ matrix considers products on one side and production processes on the other. This means that the process of identification is decoupled in two dimensions. This highlights a completely different approach compared to the ones seen so far. While other criteria consider just one attribute a time, subnetworks must look at activities from a twofold simultaneous perspective: products and manufacturing processes. The double perspective of subnetworks introduces a brand new idea over the categorization of manufacturing networks. Furthermore, for each axis (product and process), more than one dimension is analyzed: in fact, complexity and proprietary information are required for both product and process. The weighted evaluation of complexity and proprietary information of products will thus provide a unified measure for positioning the subnetwork on the x-axis. Similarly for complexity and proprietary information of processes on the y-axis.

C) Necessary conditions: there are no indications in literature on what is the maximum number of plant or level of activities that can be included in a subnetwork. It would be too simplistic to provide some average measures of the size of subnetworks within IMNs. In the same way, literature does not explicitly show any minimum level of activities for a subnetwork to exist; however, we can say that at least one subnetwork must be identified in a network. It means that the variability among products or among processes is so limited that manufacturing activities cannot be split into multiple groups. In that case, the subnetwork corresponds exactly to the network. In addition, taking the perspective of one single subnetwork, the extreme scenario is the one in which a single plant represents one subnetwork, if all the manufacturing activities of a specific group of products are condensed in it

D) Products types: the granularity with which we look at the product portfolio of a company needs additional clarification. Products within a manufacturing organization can be observed through different levels of analysis, i.e. product types, product categories (or product groups) and products (lowest level). Starting from the more aggregate level, products can be divided into different product types, i.e. macro groups of goods with rather similar characteristics, a similar architecture or business objectives, for example, software and hardware. A product type can be divided into several categories. For instance, software may be sub-divided into Business software and Educational software categories. Each product category can further be disassembled into sub-categories up to the lowest level, represented by the single product. A single product in any company is identified by a unique code. Especially in recent years, product customizations lead to a multiplication of codes, i.e. products. International companies have a business diversification that leads them to produce goods that are very different from each other, in different businesses and even in different industries; medium-sized companies can have tens or hundreds of thousands of codes in their portfolio. Thus, it is also intuitively difficult to identify a subnetwork as a set of plants working for the same product group. The most appropriate attribution is that different subnetworks are identified by specific product families, i.e. product types. Products within the same type derive from a common platform, have similar characteristics and use same (or similar) production processes; furthermore, they might share the marketing strategy as well as customer segments or distribution channels. Subnetworks will thus be identified by looking at different product
types. The identification of product-types can give a first glimpse about the characteristics of the products (complexity, technological level, technical features, etc.) and so help in the phase of identification of subnetworks.

E) Plants or activities: previous research about subnetworks have always dealt with the analysis by dividing the network into subsets of plant and not in subsets of manufacturing activities. In other words, the plant has been considered as the minimum unit of analysis, that cannot be in turn disassembled into smaller entities. However, there is a clear indication that a single plant can be part of more than one subnetwork if it answers simultaneously to more manufacturing missions. This means that a single plant can produce more typologies of products and this will be identified by the detachment of the plant in different manufacturing areas or production lines. For this reasons, to avoid wording problem, we suggest that a subnetwork can be identified as a set of plants that are partially or entirely dedicated to that subnetwork, therefore considering both plants and manufacturing activities.

Table 1 summarizes these factors.

Table 1: Summary of subnetwork characteristics

<table>
<thead>
<tr>
<th>Topic</th>
<th>Characteristics</th>
</tr>
</thead>
</table>
| A) Basic structure | - The subnetwork is a physically defined entity, including plants, assets, manufacturing processes and/or material that are grouped according to the characteristics of products manufactured and productions processes used.  
- Within a single IMN, subnetwork can be partially or completely overlapped. |
| B) Subnetworks classification criteria | - Subnetworks are divided according to products realized and manufacturing processes used, by considering for each of them the complexity and the proprietary information levels, which must be evaluated jointly. |
| C) Necessary conditions | - At least one subnetwork can be identified in a network.  
- A subnetwork is represented by one or more plants |
| D) Product types | - A subnetwork works on similar products represented by one (or few) specific product family or product type. |
| E) Group of plants or activities | - A subnetwork is a set of plants entirely or partially dedicated to that subnetwork. Thus, we can refer to it as a set of plants or activities. |

Grounded on the literature review, on the above consideration and on the clarification suggested, we propose the following definition of subnetwork:

_A subnetwork is the aggregation of a set of plants or activities that work for the same products, product families or product types and that work with similar production processes. A subnetwork is characterized by these three features:_

- **Grouping categorization:** the grouping criterion is based on the joint evaluation of multiple dimensions, that can be summarized as complexity and proprietary information of product and processes.
- **Inclusiveness:** the body of all the subnetworks in a company represents the entirety of the manufacturing production.
- **Overlapping:** subnetworks can be partial overlapped, in that a single plant can belong to more than one subnetworks.

**4. Why is the concept of subnetwork useful?**

Operations managers in today’s complex manufacturing environment require tailored and specific tools for the management of their network. It is undoubtedly true that
management models that have been successful in the past have nowadays lost part or all of their effectiveness (Friedli et al. 2014). The categorization through subnetwork introduces considerable elements of novelty. The practical implications can be reached when applying subnetworks over real industrial cases. One of the advantages is that subnetworks provide a brand-new interpretation for international companies management based on multiple dimensions; up to now, sub-groups of networks have always been created by considering one dimension at a time. Thus, the subnetwork approach provides a good insight that partially alters the former criteria for decomposing a network configuration; the topic requires additional effort to further contribute to the literature. However, the main expected advantage is that subnetwork categorization provides not only a model for the division of activities in a network but, above all, a practical framework for the management of the subnetworks created, in order for them to be more efficient in their production missions. The model is particularly effective for the plants’ localization, in that it provides additional insights and help in orienting the movements/relocation of factories, especially in the case of Rooted subnetworks.

We analyze in particular the approach and the challenges that the introduction of subnetwork could bring to three different elements that support the company’ strategy: the role of the plants, the theme of capabilities and the manufacturing strategy.

4.1. Role of the plants

The first topic that connects to the subnetwork concept is the one about the role of the plants within IMNs. The connection is clear in Ferdows et al. (2016) when discussing the duties that the different plants need to reach, and it is far more evident when introducing the concept of congruency in networks or subnetworks. A wide branch of literature on IMN has been dedicated to the specific role of plants in international companies. Skinner (1974) and Hayes and Schmenner (1978) can be said to be the precursors in theory about plants role. Multiple models and framework about the role of the plants have developed over the years. Ferdows, 1997; Cheng and Farooq, 2018; Cheng and Farooq, 2018; Feldmann et al., 2013; Cheng et al., 2011b). The subnetwork perspective enlarges and reconsiders the frameworks of the classification of value networks. The role of the plant is no more developed according to the whole network mission, but studied for the accomplishment of a narrower entity (subnetwork), with more specific and clear needs. Furthermore, Rooted and footloose subnetworks typically have completely different commitments and thus the role of the plants within them could change accordingly. In this perspective, the subnetwork approach separates the concept of the plant's role from the overall company's production mission.

4.2. Network capabilities and plant capabilities

A wide literature about capabilities in the topic of operations has been developed over the years, from both a firm perspective and a network perspective. Starting from pioneer study of Porter, 1980 about the competitive forces approach, literature analyzing the technological, organizational and managerial capabilities inside the firm was developed (Colotla et al., 2003; Voss and C.a., 1995). Other researchers (Teece, 2018; Teece et al., 1997) shed lights on the dynamic capabilities, in regimes of rapid changes. The attention to global network capabilities has raised in the last decades. The transition to a global competition for most of the industries has led researchers to focus their attention over the network capabilities with the aim of building competitive advantage. (Bartmess and Cerny, 1993; Shi et al., 1997). Despite the large amount of literature related to network capabilities and plant capabilities, the two elements have usually been treated like different components. The introduction of subnetworks narrows the distance between plant capabilities and network capabilities. Factory and network level capabilities have shown to mutually affect each other and to simultaneously affect a series of operational
performances and dimensions (Colotla et al., 2003). While for individual plants the competitive advantage can be measured by a series of operational performance indexes, the capabilities from a network perspective need to evaluate a wider range of elements. The introduction of subnetwork can thus shed light on the interdependencies between firm and network capabilities, and it can suggest management models that take into account the relationship between firm and network capabilities.

4.3. Manufacturing strategy
One of the most important tasks of executives in a manufacturing company is to select a mission for the business in order to determine how the company will compete in the long run. Although literature about manufacturing strategy uses slightly different dimensions and terminology, the strategic configurations proposed are actually quite similar (Cagliano et al., 2005), converging on four types of strategic configurations, i.e. market-based, product-based, capability-based, and price-based. More recent researchers (Chatha et al., 2015; Friedli, 2014) classify the six fundamental factors in the manufacturing strategy as: quality, price, reliability, flexibility, service and innovation. The interest about manufacturing strategy has shifted in the last decades from the investigation of the single company, to the analysis among organizations, in particular in emerging economies (Chatha et al., 2015)

However, what emerges from the literature over manufacturing strategy, is that the analysis has generally been directed to the network as a whole, an rarely to subsets of it. The basic assumption that links subnetworks to manufacturing strategy is that the strategic choice of manufacturing strategy can be bounded to specific product types or family of products. In other words, the differentiating factors in a company can vary from a subnetwork to another. For instance, some plants have the manufacturing goals to be highly productive and highly efficient to stress the price factor, others could be more oriented to flexibility or quality drivers. Thus, we can analyze the manufacturing strategy assuming that different subnetworks would need divergent manufacturing factors.

Table 2 provides a synthesis of the above considerations.

<table>
<thead>
<tr>
<th>Theme</th>
<th>Why should the subnetwork perspective be useful?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Role of the plant</td>
<td>- Subnetwork approach can untie the concept of the plant's role from the overall company's production mission</td>
</tr>
<tr>
<td>Capabilities</td>
<td>- Subnetwork approach reduces the distance between plant capabilities and network capabilities, allowing to deepen the interdependencies among them</td>
</tr>
<tr>
<td>Manufacturing strategy</td>
<td>- Subnetworks can untie the manufacturing strategy from the overall company vision. - Possibility of interpreting differentiating factors through a combined process-product criteria</td>
</tr>
</tbody>
</table>

The above considerations shed light on new research challenges, i.e. unsolved questions, and, on the other hand, on a series of potential new interpretative approaches and solutions to the topics. Table 3 provides a first glimpse of them. Surely, the identified challenges and interpretative approaches need further research.

<table>
<thead>
<tr>
<th>Challenges</th>
<th>Interpretative approaches</th>
</tr>
</thead>
<tbody>
<tr>
<td>Role of the plant</td>
<td>- How does the role of the plant change if analyzed at a network or at a subnetwork level? - Roles of the plant can be tailored over the subnetwork, according to specific needs</td>
</tr>
</tbody>
</table>
- A single plant can have multiple roles
- A single subnetwork can require a plurality of roles.
- The type of subnetwork influences the roles required

Capabilities
- Do subnetwork capabilities exist? - How do they differ from individual sites capabilities and from network capabilities?
- Are the network capabilities coherent with the manufacturing mission when introducing the subnetwork analysis?
- Improved alignment between plant capabilities, subnetworks’ objective and corporate vision
- Better management of the trade-off relationships between plant and network capabilities and among different network capabilities

Manufacturing strategy
- How can we integrate the manufacturing mission of a company with the subnetworks specific objectives?
- How and how often do the manufacturing strategies of subnetworks change?
- Co-existence of different manufacturing strategies in the same organization
- More frequent changes in subnetworks’ manufacturing strategies

5. Conclusions
In recent years, IMNs have seen their marginality stretched to the limits, especially in developed countries. The attention of IMNs has passed from the analysis of single plants to the analysis of the network as a whole. In this context, analysis over the intermediate level is still scarcely developed. As managers strive to improve the performance of their organizations, they also need to use a common language to conform their organization to the most recent standards. In the perspective of heightening the creation of a common dictionary within IMNs, our paper aims at developing a structured and comprehensive definition of the concept of “subnetwork”, as firstly hypothesized by Ferdows et al. (2016). The conceptualization of subnetworks has proved to be complex and multifaceted. The concept of dismembering an IMN into aggregates of plants with common characteristics is not new and has been addressed in the literature from different perspectives. Our work is not only a pure attempt of formal linguistic definition, but it proposes key criteria for the existence of subnetworks.

The research contribution is indeed given by the conceptualization, modeling and precise explanation of what we mean by productive subnetwork. Literature about IMN has given a first generic definition of subnetwork, but without adequate formalization and clarity about what a subnetwork really is. The importance of subnetworks is that they reinterpret the typically codified hierarchical understanding of relationships between different “parts” of the company, by fractioning the company into partially overlapped parts.

Our insights give emphasis on three basic characteristics: first, the non-uniqueness of the dimensions through which grouping plants and activities; the subnetworks consider two distinct elements (product and process) simultaneously and it is in contrast with all the other grouping criteria found in the literature. Second, the fact that on each dimension more than one factors need to be evaluated; third we point out the differences compared to other criteria (network and business units).

Furthermore, we provided evidence of the practical relevance and the additional contribution of subnetwork approach, by identifying the reasons why subnetwork is useful considering three core topics in IMNs: role of the plants, capabilities, and
manufacturing strategy. Moreover, we identified a series of unsolved challenges and potential interpretative approaches for each topic.

This research, therefore, seeks to encourage a debate in the academic and practitioner communities regarding the main characteristics of subnetworks. The derived considerations can be enlarged to further discussions. In particular, what we assume to be interesting in this perspective is the analysis of the questions and open points that have been raised, and the investigation of the elements that allow companies to position the identified subnetworks into a coherent general framework. These points would need additional research.

Abstract

This study presents a novel “hybrid” strategic sourcing framework, designed and developed in collaboration with a leading international company in the tyre industry using a design science approach. We present the main insights related to the structure of this new framework and its key constitutive components. We discuss the preliminary implementation in the company to highlight its key features in supporting purchasing managers in the coherent decision-making process through a comprehensive analysis of buyer-supplier relationships, based on the identification of the optimal number of suppliers, the analysis of the power balance and competitiveness, and the evaluation of internal complexity.

Keywords: Strategic sourcing, Framework, Implementation

Introduction

Despite providing several theoretical models to manage buyer-supplier relationship (e.g. Olsen and Ellram, 1997), the literature on strategic sourcing still lacks of practical examples of the implementation of coherent instruments able to guide companies along the strategic sourcing journey (Formentini et al., 2018): in other words to make available
to purchasing managers integrated tools to trace a route, i.e. identify the most strategic suppliers and develop specific tailored plans, control the route and if the route has not been followed, check results and take action, thus providing a feedback loop for control and correction of actions.

Considering this relevant academic and managerial need, in this study we focus on the development and implementation of a strategic sourcing framework able to integrate these three main key steps. The main objective of the proposed framework is to provide overall coherence and balance throughout the entire strategic sourcing process. This study focuses on the analysis and discussion of the implementation of the proposed strategic sourcing framework in the partner company through the evaluation of one case of application of the framework performed in 2017 and 2018. We build our analysis both on data collected in the partner company throughout the design science process. One of the key objectives of this study is to discuss the hybrid framework as a “methodology” suggested to purchasing managers in other organizations and therefore allow generalizability of the model. We aim at discussing the innovative elements of the proposed framework (i.e. the calculation of the optimal number of suppliers, evaluation of power balance between the parties, etc.) and its theoretical underpinnings (e.g. complexity theory).

Our study contributes to the Purchasing and Supply Management literature by offering detailed insights on the design, development and implementation of the framework, providing managers with an integrated tool to support coherent decision-making and refining previous studies in the field (e.g. Formentini et al., 2018) by offering a more in-depth analysis of the strategic level concept, and a stronger connection between relevant perspectives, i.e. power balance and internal complexity. In terms of managerial implications, we believe our framework offers purchasing managers a comprehensive set of factors to be considered in the complex strategic sourcing process, ultimately leading to meaningful and coherent decisions in managing the supplier portfolio.

Theoretical background
Formentini et al. (2018) have recently addressed the gaps in the Purchasing and Supply Management (PSM) literature related to the implementation of purchasing portfolio models (e.g. Olsen and Ellram, 1997) in an integrated manner to support purchasing managers’ decision making throughout the different hierarchical strategic levels (i.e. from business strategy to purchasing strategy, and in turn specific differentiated actions towards suppliers) in line with the “strategic alignment” research by Hesping and Schiele (2015) and Gonzalez-Benito (2007).

Building on the integration of three different purchasing portfolio models (i.e. Kraljic, 1983; Olsen and Ellram, 1997; Scoot and Westbrook, 1991), the strategic sourcing framework integrates three relevant theoretical perspectives, to provide a comprehensive understanding of strategic sourcing decisions considering Transaction Cost Economics, Social Exchange Theory and Resources Dependency Theory, as interconnected lenses. However, in terms of limitations, this framework is providing only a partial discussion of key factors, such as the detailed measurement of each suppliers’ strategic role, and the current level of power balance characterizing specific buyer-supplier relationships.

Moreover, another important academic and practical gap is still represented by the possibility to evaluate the effective impact of these strategic purchasing decisions on performance results – given the complexity of factors influencing business performance and competitiveness - and the development of specific capabilities (Gonzalez-Benito, 2007; Knoppen and Sáenz, 2015) to support managers in strategic purchasing. It is challenging for companies to trace a route for strategic purchasing decisions, control and
take actions. We believe that the PSM literature has so far provided important insights but the main approaches are still “fragmented” and need to be integrated for more coherence and impact. Hence, we propose a new “hybrid” strategic sourcing framework, able to integrate several perspectives emerging from the PSM literature and practice.

**Research design**

The proposed strategic “hybrid” sourcing framework has been designed and developed through a design science research approach (Denyer et al., 2008; van Aken et al., 2016), building on recent studies (e.g. Formentini et al., 2018) and established literature on purchasing portfolio models (Olsen and Ellram, 1997) and strategic sourcing (Hesping and Schiele, 2015; González-Benito, 2007). In line with the action research method, the research objectives have been iteratively refined in order to integrate the specific needs of the partner company collaborating in this study - a leading international firm in the tyre industry - facing the need to develop a novel strategic sourcing approach for coherent decision-making. Initially, the study started by focusing on the identification of an optimal number of suppliers for a specific purchasing context; in the following iterative steps, it became clear that it was required to understand and integrate several different perspectives, beyond the initial focus on the optimal number of suppliers. Therefore, in this study we aim at answering the following research question: “What are the key drivers influencing the selection of a coherent supply base size at the strategic level?”

As a result, this study focuses on the development of the proposed framework – driven by the research question - and its key constitutive components. We also provide a preliminary analysis and discussion of the implementation of the proposed strategic sourcing framework in the partner company through the evaluation of one case of application and prototyping of the framework performed in 2017 and 2018. As a result of the close collaboration with the partner company, we build our analysis and discussion both on qualitative (i.e. interviews) and quantitative (i.e. sourcing and performance data) collected in the partner company. One of the key objectives of this study is to discuss the hybrid framework as a “methodology” suggested to purchasing managers in other organizations and therefore allow generalizability of the model. We aim at discussing the innovative elements of the proposed framework (i.e. the calculation of the optimal number of suppliers, evaluation of power balance between the parties, etc.) and its theoretical underpinnings (e.g. complexity theory).

**The need to define an optimal number of suppliers**

The proposed framework has been developed in close collaboration with the partner company, aiming at providing support in a complex and challenging decision-making scenario and understanding the key trade-offs that characterize this context. Following an action research approach, we performed a literature review in the strategic sourcing literature to identify the availability of comprehensive frameworks able to support the company in defining an ideal number of suppliers, in line with the recent trends highlighting supplier base reduction, rationalization and optimization; it was possible to identify a limitation of the literature in terms of guidelines for the evaluation of relevant strategic suppliers, and in turn the identification of an optimal number of suppliers, especially to identify a coherent amount of incentives to allocate to the specific buyer-supplier relationship. A clear understanding of the variety of factors to be considered was lacking in the related literature.

When reviewing the literature, we noticed that the selection of the ideal number of suppliers is deeply linked with the decision of the sourcing strategy selected. Considering the main findings in the strategic sourcing literature, however, it seems that the most
important and relevant recent trends are characterized by the reduction of the number of suppliers. In fact, the majority of studies suggest that in order to effectively increase long-term and mutual co-operation with best performing suppliers, and to cope better with the strategic objectives pursued by the buyers, it is necessary to reduce the size of the supply base, and to allocate higher amount of resources to the remaining suppliers. In general, in fact, buyers’ resources are limited, and highest efforts should be allocated only to most strategic suppliers, while on the other hand no-value adding suppliers should be eliminated from the base. For instance, Dowlatshahi (2000) focuses on the main reasons for the need of supply base reduction. Supply base reduction approaches are used to reduce the size of the base by eliminating the worst suppliers currently in the set, as discussed for instance by Monczka et al. (2002). However, the main studies are missing to investigate which is the optimal number of suppliers to maintain, providing indications towards the elimination of low-performance suppliers. In a similar vein, supply base rationalization (Dubois, 2003) and supply base optimization (Talluri and Narasimhan, 2005) provide insights on this reduction and focalization process.

Following this consideration, it became clear that the study should require specific considerations and analysis about the number of suppliers to include within a differentiated and strategically managed portfolio. Therefore, it is important to include in the research objective a supply base rationalization process, where the interest is not only to define a model to select the best suppliers, but also to have a clear and numerical indications on how many suppliers must be selected and managed; this is confirmed by the fact that the partner company was actually shifting from a decentralized to a centralized purchasing structure, and in this evolution process too many suppliers had been identified, thus requiring rationalization.

However, it is really important to note that supply base reduction activities may also not perform as planned, since not always the decision to simply reduce the number of suppliers could be intended as the best solution to improve the sourcing strategy potential, as well as there is no guarantee that higher collaboration will be achieved with the single supplier selected. Furthermore, other considerations must be examined, since this strategy may also impact on buyer’s cost structure even in the medium-long-term differently as forecasted: if strategies are not correctly designed and the buyer only focuses on immediate operational cost reduction opportunities related to a business relationship with only one supplier (the lower the number of suppliers, the lower the coordination and operating costs), it could be risky to ignore some other highly important and linked cost considerations which may affect and harm buyers’ cost structures on a long-term basis. For example, dealing with supply base rationalization processes, if the buyer solely focuses on selecting few, high performing suppliers, besides the theorized and hypothesized advantages described above, the buyer could experience low differentiation within the supplier base: “ignoring this consideration could leave a firm undergoing supplier rationalization with a smaller but more redundant strategic supply base” (Talluri et al., 2013). Additionally, a reduction in the supply base size would imply several consequences: buyers would increase their dependence level towards suppliers, and if they are not able to shift to a balanced power level, they may suffer of decreased performances and higher prices (Cousins, 1999).

In summary, even if the global trend seems to benefit and prefer supply base reduction activities, it is not clear whether there is any guarantee that a single sourcing strategy will perform better than a multiple one. Therefore, we decided to refine the focus of our study to develop a more in-depth understanding of the key factors influencing the identification of strategic suppliers, their ideal number, and in turn the recommended actions suggested
to managers in allocating incentives for the improvement of specific buyer-supplier relationships, in order to manage the power balance and dependence.

Towards the development of the “hybrid model”

As a result of the close interaction with the company and the continuous review of the strategic sourcing literature, it was possible to identify a trade-off including three main indicators, as represented in Figure 1, i.e. 1) the focus on strategic suppliers, 2) the competition level and 3) the internal complexity. It emerges that a comprehensive understanding of the optimal focus in strategic sourcing decisions should take these three indicators simultaneously into account.

Figure 1 - Trade-off and coherency approach of the indicators within the hybrid model

Focus on strategic suppliers

Supplier portfolio models suggest that the resources available in the procurement department are limited and should be allocated mainly to the most strategic relationships. In general, the higher the focus on strategic suppliers, the lower will be the number of suppliers included in that context. As shown in the literature by qualitative models, a high focus on strategic suppliers will be beneficial for the buyer, since it allows to focus on best performing ones, reaching volume and learning cost reduction effects, high-valuable co-design activities and high level of incentives to co-operate effectively together.

In practice, this analysis requires the consideration of two dimensions:

1. The strategic level – i.e. how much each supplier is considered as “strategic”, according to the buyer’s criteria;
2. The incentive level – i.e. how much the buyer is currently investing resources in a specific relationship with a supplier.

In other words, the concept of coherence and the findings of power balance are integrated to highlight several major points, fundamental in the analysis performed:

- Focusing on less suppliers allows for higher volume shares to the selected suppliers, to gain competitive advantage;
- The portfolio should be managed coherently, in order to allocate the right level of resources in relation to the importance of the specific supplier (power balance adapted results);
- Differentiation in the supplier portfolio is required (heterogeneous product portfolio and purchasing category require numerous suppliers to be differently managed).
Thanks to this indicator the purchasing manager can investigate if he is coherently managing, in terms of volume share and relationship’s investments, its supplier base according to the strategic level attributed to the suppliers, in terms of their potential performances and capabilities values. After the high-level framework has been set, it is necessary to effectively define two ways to calculate the two aspects considered: specifically, it has been decided to include the strategic score to convey the strategic relevance of a supplier within buyer’s considerations, while to build a new tool, the incentive level, which ideally represents the importance that the buyer is attributing to each supplier.

The basis of the focus on the strategic suppliers’ indicator is that coherence is obtained if a proportional level of incentives is attributed to suppliers in relation to their strategic score value.

According to these findings, quadrants in Figure 2 are represented with three different colors:

- The green quadrants are the most coherent cells, since the suppliers are managed coherently and accordingly to the importance of each of them;
- The yellow quadrants consist of situation of low incoherence, which could be solved relatively easily with little and specific changes;
- The red quadrants are the most dangerous situations, and are the ones which require the highest attentions, since it is possible to find suppliers very strategic but allocated with a very low volume share or contract importance, or vice versa.

Given these general categories, it is not difficult to imagine that a coherent sourcing strategy will generally depend on how coherently these two dimensions are managed: the more the suppliers in the green zones, the better it is. However, it is also important to remark that the coherence zone is not static and fixed, and adapt itself to the context and to the general position of suppliers within the base: because of this, the purchaser will need each time to assess, looking at the matrix, how much coherent is the current situation.

**Competition level**

Considering that the first indicator could effectively push for a reduction of the supply base size, the second indicator has been selected in order to counterbalance this effect.
Specifically, literature review states that, among all the possible effects, a supply base reduction may lead to two major effects:

a. Transfer of power from buyer to suppliers, with all the related consequences (higher risks, lower potential performance and commitment);

b. The reduced competition level would consequentially lead to a loss of performance and results obtained by the suppliers.

Because of these reasons, this second force, the competition level, can be logically intended as a force effectively pushing towards an increase of the number of suppliers, since the higher the number of suppliers in the base, the higher the potential competition level obtainable by the firm. This can be effectively seen as an assumption made by the model: it is modeled that higher competition directly impacts on a decrease of the risk and dependency level.

To improve the business’s impact of the indicator developed, it has been searched in the literature a quantitative tool suitable to calculate this parameter: in particular, it has been found that the Herfindahl-Hirschman index (HHI) (Rhoades, 1993) seems to be perfectly adapt to the use required. The HHI is in fact a commonly shared industry ratio generally used to assess the concentration level of a market: the concentration level ratio is used to assess how much the market, in terms of volumes shares to the supplier, is concentrated, where the monopoly is intended as the most concentrated market structure, in opposition to the perfect competitive market, which is the lowest concentrated market, since all the suppliers share the same demand allocation. Since the aim is to calculate competition and not concentration level, however, this can be measured by evaluating the complementary of HHI, since the two measure are one the opposite of the other.

![Figure 3 - Normalized competition level for a sample of selected sourcing strategies](image)

This is also a good way to highlight how much importance is not only allocated to the number of suppliers selected, but also on how the demand has been splitted among them; furthermore, a big role is also played by the number of the available suppliers, and not only the ones effectively selected by the firm, and which have not been allocated of a specific order: their impact must be effectively considered within the normalized HHI analysis.

Interestingly, even if the two described forces could be sufficient to solve the problem, they mainly consider an external scenario, while also internal considerations must be investigated. This is necessary since a specific competition level and focus
towards more strategic suppliers, besides the advantages and disadvantages described, would impact differently on the buyer’s general management efforts, in terms of number of suppliers to manage, as well as items and plants/countries served by the company, as discussed throughout the action research process when considering the different impact on operating and management costs caused by the size of different supply bases. Because of this specific company need, a third dimension has been introduced in the proposed framework, i.e. the internal complexity dimension.

Internal complexity
The internal complexity index measures the actual variety managed by the buyer, considering the dimensions under direct control. This indication is very useful for managers since it allows them to balance better the trade-off among the two forces above described. In fact, as will be shown later on, high level of performance both in strategic and competition levels must be reached through a coherent definition of the internal complexity level. Interestingly, within the internal complexity indicator, it is possible to individuate another intrinsic trade-off analysis between managerial costs and network potentials. In fact, the logic under this decision is that if it is generally assumed that higher variety to manage could be an additional burden to be controlled and monitored, with a consequent conversion into higher costs to sustain for generally no value-adding activities, it may also be noted that a certain level of variety is not only necessary, but could also be a source of advantage for the firms. For example, it could improve the resilience’s level of the firm, which generally can be intended as flexibility and capability to overcome and solve eventual risks and issues within the network, especially in case of emergency, which is fundamental in a wider and graphically dispersal supply base, but also adaptability possibilities, in terms of higher capability to change the internal structure, to switch suppliers or access to better resources, technologies and other factors.

**Figure 4 – Relationship between internal complexity and performance levels**

In a similar way to the strategy used during the definition of the competition level and the HHI, a meaningful research has been performed to find out if some business tool could be effectively used in this decision. An interesting parameter used to calculate the
uncertainty level is the Shannon’s Entropy index. This is a tool designed to measure the uncertainty level within a system; the higher the uncertainty, the higher the entropy level.

Because of this, the decision is to calculate the internal complexity by calculating the product of three factors: the suppliers included in the base, the average number of items each supplier is sourcing and the average number of plants/countries each supplier is shipping to. The higher this product, the higher the internal complexity to manage, the higher the cost.

Discussion of findings
The “hybrid” framework has been converted into a decision support tool in the company, able to identify the three proposed strategic decision drivers, combine them and provide their quantitative measurement. It evaluates the current “as-is” scenario, providing a holistic monitoring and control through the use of several dashboards.

We are currently studying the developments related to the integration of the proposed framework in the procurement planning process in the partner company – which is very evolved, and characterized by a high level of formalization - which first of all starts with a “long-term planning” phase. This first step is not aiming at taking decisions, but ultimately at understanding the cost plans with a 3-year horizon, since the homologation processes for new products are usually very long and they can require up to 18 months, for instance, when purchasing a new material from a new supplier. Adopting this long-term perspective, we have integrated in our framework the key insights from the original model by Olsen and Ellram (1997), following this approach to measure the “level of strategic importance” of a specific supplier.

Future developments of this study will focus on the theoretical discussion of the “hybrid” strategic sourcing framework, a tool to combine three key perspectives:
- Strategic perspective – i.e. alignment and coherence, and focus on key strategic suppliers aiming at the development and improvement of strategic buyer-supplier relationships;
- Competition and power perspective;
- Complexity perspective.

Conclusions
This study contributes to Purchasing and Supply Management theory and practice by discussing the novel “hybrid” strategic sourcing framework able to support and guide managers in developing coherent decisions to manage suppliers and in turn allocating incentives, e.g. volume share. This contributes to the literature on strategic purchasing and alignment (e.g. Hesping and Schiele, 2015; González-Benito, 2007). Moreover, the new hybrid model contributes to theory by providing a deeper understanding of the strategic sourcing trade-off, i.e. balancing the focus on strategic suppliers and suppliers’ power (Caniëls and Geldermann, 2007). The hybrid model is composed by three indicators (i.e. focus on strategic suppliers, competition level and internal complexity) which are integrated to grasp the key factors, such as the supply base size or the volume share, clearly visualizing the current scenario faced by the firm. These indicators have been developed and included in the framework prototype currently implemented in the company in order to offer a good level of inter-connection among the dimensions considered. Summing up these considerations, this study contributes in analyzing a complex decision-making scenario, which has been overlooked in the strategic sourcing literature, missing to provide a “hybrid” approach able to integrate both quantitative and qualitative analyses, especially providing a practical tool for implementation.
From a managerial point of view, this study provides useful recommendations to purchasing managers through the development of a decision support system to facilitate managers in the allocation of resources to suppliers, leveraging the managers’ experience with tailored decisions in line with the three integrated perspectives (i.e. strategic focus; power balance; complexity).

Abstract

Offshoring emerged as a major business practice since the 90s. Recently the phenomenon seems to be affected by the decrease in cost advantages of developing economies, the consequences of the 2008/09 economic crisis and the advent of new technologies (Industry 4.0). This paper investigates how offshoring geographies and drivers have changed over the last fifteen years. Based on a longitudinal analysis, we identified three different phases. Specifically, while the number of offshoring cases progressively decreases, we observed that location decisions are less driven by cost-related motivations and more by technological and market-related drivers.

Keywords: Offshoring, Reconfiguration, Drivers

Introduction

In last few decades manufacturing offshoring – the transfer of production activities from home country to foreign locations (e.g. Ferdows, 1997; Feenstra, 1998; Lewin et al., 2009) – has emerged as a major industry trend and, at the same time, as a popular research topic in operations management (OM) and international business (IB). Literature has shed light on a wide set of offshoring issues, such as definitions, motivations, drivers and outcomes (e.g. Lewin and Peeters, 2006; Schmeisser, 2013; Hernández and Pedersen, 2017).

The temporal analysis of the European industrial system shows that in recent years location choices have gone through a transformation. Initially, a massive transfer of production took place. The main motivation was the research for cost advantages (e.g. Aubert et al., 1996), especially in high labour and low-tech industries (e.g. apparel and furniture) or where price-based competition prevailed. As time went by, firms realized that offshoring had not only advantages but also a number of initially unexpected costs and risks (Patrucco et al., 2016; Herath and Kishore, 2009). For this reason, companies
began to reconsider their choices with the growth of phenomena such as right-shoring and reshoring.

Nowadays, comparing with the past, the global chessboard appears deeply different due to a series of exogenous factors that are changing the drivers and therefore the geography of location choices. Among the others we can cite: the production overcapacity in Western countries (determined by the global crisis), the increase in prices in key developing countries e.g. China (Simchi-Levi et al., 2012; Arlbjørn and Mikkelsen, 2014) and the new technological trajectories, e.g. industry 4.0 (Rüßmann et al., 2015; Fratocchi, 2017; Ancarani and Di Mauro, 2018).

While the inter-temporal approach is well rooted in IB internationalization research (e.g. Lewin and Volberda, 2011), there are so far no OM studies which analyse the temporal evolution of manufacturing offshoring. This paper is aimed at solving this gap by offering an evolutionary perspective of offshoring and highlighting its evolving geography and drivers.

The study is based on the European Restructuring Monitor database (https://www.eurofound.europa.eu/observatories/emcc/erm/factsheets), that consists of secondary data related to 29 nations (28 EU members and the Norway). The used sample consists of 669 offshoring cases.

As far as the methodological approach is concerned, we employed different statistical tools in order to fully explore several aspects. First, we looked for discontinuities in the data (Kleiber et al., 2002) to define temporal milestones. Then we performed network analysis to assess the geographical evolution of the phenomenon and understand if involved countries have changed over time. Finally, exponential random graph models (ERGM) (Hunter et al., 2008; Kolaczyk and Csàrdí, 2014) allowed us to understand which determinants are considered by the firms for their location choices and connect the relocations to the drivers.

Assuming a time dependent variable we are able to show an evolution of the offshoring phenomenon through three different time intervals and to identify some underlying mechanisms that drive specific global sourcing patterns: determinants of the phenomenon have changed over time shifting from a cost- to a market- and technology-seeking perspective.

Literature background and question development
There is a wide literature focused on offshoring. It sheds light on several issues such as: motivations, geography, firm performances and risks of the phenomenon. The considerable interest in the phenomenon is due to the fact that since the 90s offshoring has emerged as one of the most widely pursued location strategies by Western companies in order to increase or at least maintain their competitive advantage (Contractor et al., 2010).

Some studies have tried to analyse the offshoring motivations. In this context, the reference model is the Ownership-Location-Internalization (OLI) paradigm, which provide insights into foreign direct investment decisions (FDI) (Dunning, 1988; Rugman, 2010):

- Efficiency seeking: firms that take advantage of cost differences in traditional production factors, or otherwise that "take advantage of economies of scale and scope" and differences in consumer tastes (Dunning, 1993; Bevan and Estrin, 2000; Kinoshita and Campos, 2003).
- Resource seeking: firms offshore to have access to high quality resources not available in the home country e.g. natural resources (Hart, 1995), human capital
(Karakaya and Canel, 1998) and knowledge related resources (Alcácer and Chung, 2007; Mudambi, 2008).

- Market seeking: firms aim to penetrate new markets. FDI is also often used to overcome customs barriers, countertrade requirements (Nassimbeni et al., 2014), special regulations (Bozarth and McDermott, 1998; Shi and Gregory, 1998) and to serve key customers (Ellram et al., 2013; Kinkel, 2012).

A second stream of research of offshoring literature is focused on the geography of the phenomenon. While the geographical context has evolved considerably over time – let us think for instance to the 2004 EU enlargement (Buckley and Casson, 2009; Onaran, 2011; Casson, 2013) – we do not find many contributions about this topic. Among the few available we can mention: Merino (2017) who has studied how important offshoring and relocation strategies are in terms of economic activity across different European regions and Cusmano et al. (2010) who shed light on the impact of offshoring on the industrial geography of Lombardy.

Third, previous studies mentioned various performance implications of offshoring, such as the development of foreign sales activities (Bozarth et al., 1998; Shi and Gregory, 1998), the improvement of delivery performance (Frear et al., 1992) and the impact on R&D performances (Lampert and Kim, 2018; Steinberg et al. 2017). The improvement of products quality is also highlighted by some studies, but this is a niche which only affects some specific countries and industries (Ettlie and Sethuraman, 2002).

Finally, the literature is not exempt from the description of risks and problems related to offshoring practices. Among the most important there are: country risk (e.g. Meldrum, 2000), risks of transfer of know-how (e.g. Ranganathan and Balaji, 2007; Gewald and Dibbern, 2009) and risks related to the quality of production (e.g. Bahli and Rivard, 2005; Belcourt, 2006). Some of the problems highlighted above could help to explain recent changes in phenomena with even the appearance of reshoring (Fratocchi et al., 2014; Ancarani et al., 2015; Fratocchi, et al., 2016; Di Mauro et al., 2018) or more in general of relocation of second degree (Albertoni et al., 2017).

The analysis of the motivations and of the few studies on geographic implications of offshoring point out that there has been an evolution in the phenomenon. The evolutionary perspective is inborn and revisable in many disciplines of economic and managerial studies, first and foremost in the IB field. Among the others, we can cite the following IB studies: Lewin and Volberda (2011), that tried to develop a co-evolutionary offshoring decision model, Lahiri and Kedia’s (2011) that studied the co-evolution of institutional and organizational factors in explaining offshore outsourcing and Youngdahl and Ramaswamy (2008) that examined the evolution of roles in offshore operations. However, as far as the internationalization of production is concerned, there are few studies that empirically shed light on whether and how this phenomenon has changed over time.

For this reason, we developed the following research questions for our study:

RQ1: Has the offshoring phenomenon changed over the years?
- RQ1A: Have offshoring drivers changed over the years?
- RQ1B: Has offshoring geography changed over the years?

Methodology

Database European Restructuring Monitor

The main source of information for our study is the European Restructuring Monitor (ERM) database. Made by Eurofound (the European foundation for the Improvement of Living and Working conditions) using secondary data (announcements in such media sources as newspapers, magazines, specialized websites, and business press), this
database contains factsheets regarding restructurings undergone by European subsidiaries of Worldwide firms. Information have been collected since 2002 and nowadays there are more than 22000 restructuring events that cover 29 countries (28 EU members plus Norway).

The unit of analysis is the single restructuring decision. Therefore, each firm may have made several restructurings and thus appear in several records of the database, each containing: size, headquarter country, industry, year of the event, number of jobs involved, home country, destination country and the motivations.

It is worth pointing out that an event is included in the database only if involves the loss or creation of at least 100 jobs, or alternatively if it concerns at least 10% of the workforce in production facilities employing more than 250 people.

The ERM database has already been used in previous operations management research on relocations of second degree (Barbieri et al., 2019), task offshoring (Goos et al., 2009), graphical patterns of value chains in the automobile part suppliers (Frignant and Layan, 2009) and firm restructurings carried out in Ireland (Gunnigle et al., 2013).

Sample
The ERM database is organized into different categories according to the type of restructuring that the company has undergone. From the ERM database, we selected all the cases classified as “offshoring/delocalization” and this led to a final dataset of 669 records covering 29 countries and 34 industries. As previously said, data only consists of offshoring cases having an European country as origin. So, while outgoings flows are precise, incoming flows can only be assumed. In our specific case we assumed that all jobs lost in the origin country were fully transferred to the destination.

Data analyses
Temporal milestones detection
Usually inter-temporal studies are characterized by a certain arbitrariness due the subjective choice of milestones. However, in our specific case we used the “flat-step" approach that, analysing the average values of a given phenomenon, identifies the transition from one stage to a subsequent one with different characteristics. This methodology allows to define an empirical milestone devoid of subjectivity and has already been applied in the biological field (Ficetola and Denoël, 2006) and for studies related to climate changes (Mariani, 2006; Chiaudani et al., 2008) to verify in which years there have been structural changes in the maximum annual average temperatures of a given area over a given period. This analysis has been carried out through the package “strucchange” (Kleiber et al., 2002; Zeileis, 2005) for the statistical software R.

Inter-temporal comparison
Network Analysis is used to study complex systems of any kind, as long as they can be represented with a graph. Application fields of this technique are varied and complex and include: economics, mathematics, sociology and industrial psychology. This leads to a great variety of perspectives and approaches based on the specific target of use. Recently some studies have begun to deepen the use of this methodology also in the field of operations management (e.g., Barbieri et al., 2019; Pilkington and Meredith, 2018).
In our paper we used network analysis to provide a geographic perspective of offshoring, highlighting the countries more able to attract investments and the ones more affected by industrial restructurings.

Networks data are interdependent and generally have unknown distributions, so their statistical analysis requires care. For this reason, we adopted a particular exponential model applied to networks (Exponential Random Graph Models – ERGM) (Hunter et al.,
2008; Kolaczyk and Csàrdi, 2014) which uses permutation-based approaches and does not require an early knowledge of population and sample distributions. In the economic-managerial field ERGM was previously employed to study knowledge transfer processes (Su et al., 2010; Harris et al., 2012), alliances in product markets (Lomi and Fonti, 2012) and recruitment (Arrieta-Paredes and Cronin, 2017).

In our specific case exponential random graph models were used to analyse the determinants of relocation choices. Consistent with previous works (e.g. Buckley et al., 2007; Barbieri et al., 2019), we included in our ERGM models 5 variables associated to efficiency, resource and market seeking motivations (Dunning, 1980):

- **Gerd**: gross domestic expenditure on R&D per capita; includes expenditure on research and development by business enterprises, higher education institutions, as well as government and private non-profit organisations and is used as a proxy for the technological situation of the country.
- **LabCost**: average hourly labour cost for each country including wages, salaries and non-wage costs (employers’ social contributions and taxes).
- **GDPpp**: gross domestic product per capita at purchasing power parity used as proxy for the size of the market.
- **Ore**: ratio of ore and metal exports to merchandise exports of the country used as a proxy for the availability of resources.
- **Patent**: number of resident annual patent registrations in the country used to capture the innovation activity.

The values of the considered variables were taken from the Eurostat and World Bank databases.

**Findings**

**Temporal analysis**

Through the “sc test” of the R package “strucchange” we performed a temporal analysis of the number of cases recorded and of the number of jobs restructured (Figure 1). Results showed two empirical time milestones (i.e., 2006 and 2009) devoid of subjectivity. Based on these findings we split the dataset into three time periods:

- First period cases up to 2006 n=264
- Second period cases from 2007 and 2009 n=172
- Third period cases from 2010 onwards n=233

**Network analysis**

As far as network analysis is concerned, we defined first of all a standard coding for all the networks to compare the results. Within each graph, nodes (also called vertexes) represent different countries and arrows are the transfer of jobs. Specifically, the tail of...
the arrow is the origin country while the tip is the destination. In addition, the size of each arrow is proportional to the flows between the two nodes. We then represented the in-degree and the out-degree networks (see Table 1 for their interpretation) of the three temporal periods identified in the previous section (Figure 2).

Note: nodes have different colours and sizes:
- Red and big: countries most involved in the phenomena.
- Green and medium: countries in an intermediate situation.
- Blue and small: marginal countries.
To have a greater accuracy we choose to make the colours blend, in this way we are able to identify countries in an intermediate situation.

<td>How a country loses jobs</td>
</tr>
</tbody>
</table>

Analysing the networks, we can notice a progressive transition with marked differences especially between the first and the third period, both for the in-degree and out-degree. As far as the in-flows are concerned (left graphs in Figure 2), there is a clear downsizing of some countries over time, primarily Romania and Hungary. At the same time, it is also clear that China has lost its role of hegemony in favour of Poland. On the other hand, as far as the out-flows are concerned (right graphs in Figure 2), we can see that they mainly regard the more developed European countries. Again, there are differences over the years. In particular, the most affected country in 2002-2006 was the United Kingdom, while the most affected countries in 2010-2018 were Germany and Sweden. However, a subsequent analysis of the individual cases shows that the out-flows of these two countries belonged to companies operating in high technology or niche sectors that have moved their production to other highly developed countries such as Japan.

We then calculated the average distance between origin and destination country (Table 2). This analysis shows that the geographical dimension of the phenomenon is gradually shrinking.

Exponential random graph model

In order to shed light on whether and how offshoring drivers changed over the years, we run three exponential random graph models one for each period previously identified (Table 3).

In the first time period (Model 1 – 2002-2006), we noticed a strong significance of labour cost (LabCost=-2.99, p<0.0001). This leads us to conclude that in this historical phase firms were mainly interested in cost savings for their location choices.

As far as the second period is concerned (Model 2 – 2007-2009), cost savings (LabCost=-2.54, p<0.001) are always dominant but have lost part of their significance, while GDPpp has become significant (GDPpp=1.28, p<0.01). A possible interpretation is that companies begin to revise their strategic plans, adding to the mere research for cost savings also the research for new markets.

Finally, the situation from 2010 onwards (Model 3 – 2010-2018) appears further different. LabCost has lost its significance, while technological variables (Gerd=1.42, p<0.0001 and Pat=9.44, p<0.001) have become significant. This makes clear that determinants of location choices have changed and, nowadays, companies are more attracted by technological aspects. The variable GDPpp (1.54, p<0.001) is still significant thus indicating that market seeking is always important in firms’ strategies.

Discussion

The analyses carried out in our study showed the existence of two temporal milestones: 2006 and 2009. These two years are part of a context characterized by deep changes that have probably accelerated latent processes. Indeed, both number of cases and number of jobs restructured (Figure 1) change their trend from 2006 onwards and, although there is a local maximum in 2009, they no longer return to previous levels.

In this period the economic crisis has led to a contraction of internal European consumptions and therefore to the need for firms to enter new markets where to sell their products. This can be observed in the evolution of the geography of offshoring phenomena. A detailed analysis of Figure 2 shows that until 2009 low cost countries (e.g. Romania and Hungary) were at the centre of incoming delocalization flows and then, in the following years, they have lost their attractiveness. On the other hand, taking into account out-flows, we notice a decrease of flows from United Kingdom (Figure 2) and an increase of flows from Italy. This country is struggling to adapt itself to new possibilities offered by recent industrial paradigms (Viharos et al., 2017) and, in the last period, has seen an increase in the number of jobs relocated. Because of all these findings we can therefore state that the most virtuous countries in terms of innovation are those with the greatest ability to attract (and not to lose) firms and jobs.

Results (Table 3) showed that until 2006 (Model 1), location decisions were driven only by cost-seeking drivers. Subsequently, over the years, companies seem to have changed course and already in 2007-2009 (Model 2) motivations related to market-seeking began to appear. But, as already said, after the economic crisis of 2009 (Model 3) we saw more significant changes. Firms start to move to countries with market opportunities or technological competencies.

A possible explanation for these changes is that the new industrial paradigms (e.g. Industry 4.0) can reduce production costs (Rüßmann et al., 2015) and enhance competitiveness in the global market even without relocations. In this regard, the literature shows some examples, and, among the others, we can report the fact that substituting old technologies such as injection moulding with new ones like additive manufacturing could allow customized and cheap production locally, even in high wage countries (Atzeni et al. 2010; Buonafede et al., 2018).

In addition, as more and more firms are trying to avoid low cost competition adopting differentiation strategies, the manufacturing in low cost countries no longer seems...
compatible with choices of competitive positioning in high-end segments where quality and quick response are demanded (Grossman and Rossi-Hansberg, 2008; Kinkel and Maloca, 2009; Ritter and Sternfels, 2004, Byeong and Han-Mo Oh, 2017).

Another point to keep in mind is that, over the last 10 years, Asian countries had a strong increase of labour costs (Pearce, 2014; Wu and Zhang, 2014) and, at the same time, developed countries a significant rise of labour productivity (Sirkin et al., 2012). This brought the labour costs per produced unit between developed and low-cost countries much closer.

Based on the studies of Taglioni and Winkler (2016) we used two OECD variables - i.e., the Share of Re-Exported Inputs on Total Imported Inputs and the Foreign Value Added in Exports as a Share of a Country’s Exports - to track the GVC participation of each country. Due to space limits of the conference papers we do not report the tables, but we limit to say that these data partially confirm our findings, highlighting the same changes in terms of geography. At the moment, instead, we are still working for time milestones confirmation.

In sum, our study allowed us to shed light on the evolution of the offshoring phenomenon with reference both to the countries and the individual firms. In this regard, we could identify three main phases:

- **Expansion phase (low-cost offshoring – 2002-2006).** Firms were interested in better economic conditions (low cost countries) with a very high and growing number of reconfiguration events.

- **Reconsideration phase (low-cost and market seeking offshoring – 2007-2009).** The number of cases is still high but starts to fall and there is a first change in the drivers pursued by companies with an initial interest also for new markets.

- **Rationalization phase (optimal mix of offshore and domestic production – 2010 onwards).** The number of cases remains low and stable. But above all, a greater experience and awareness of companies in their location policies emerges. Indeed, the drivers sought by firms have changed: companies are strongly interested in technologies and new markets. Moreover, in this period new location strategies, such as re-shoring (Ellram et al., 2013; Fratocchi et al, 2014) and right-shoring (Joubioux and Vanpoucke, 2016; Abbasi, 2016) emerged.

**Conclusions**

**Contributions**

This paper has significant implications for operations management and international business research. First, the evolutionary approach adopted made it possible to develop a map with well-defined time milestones and phases of offshoring, highlighting both qualitative (driver) and quantitative (extent of the phenomenon) changes. Indeed, we pointed out that firms are moving from low-cost towards technologically more advanced countries and among different reasons we can include benefits offered by initiatives like industry 4.0 (Schönsløben et al., 2017). Second, our work provided important information on why a particular country has changed (or maintained) its position within the global location dynamics. Finally, we were able to better define some of the characteristics of recent shoring strategies (i.e. right-shoring).

The findings might also contribute to practice and policy makers. We highlighted the need for managers to have a dynamic approach of internationalization being ready to move their facilities to pursue evolving location drivers. Specifically, managers should take into account not only the initial costs to set a plant, but also any other future cost of relocating activities to another country. Furthermore, the identification and comprehension of offshoring drivers and motivations might help policy makers to find...
tools to strengthen the manufacturing base and to re-attract offshored firms, thus improving employment and GDP (e.g., investment to improve the country's technological aspects).

Limitations and future research
The results of our study should be viewed in light of some major limitations. First, we used secondary data based on public announcements of restructuring initiatives. However, the fact that data was collected by a rather reliable organization and that studies based on secondary data have already been published in the past (e.g. Elia et al., 2014) give us high confidence about their reliability. Second, Europe has always played a central role in firms’ location decisions, both in terms of offshoring and reshoring, making this region the ideal place for our study (Barbieri et al. 2019). However, excluding flows coming from extra-EU countries causes the loss of information. For this reasons, future research may include in our study also other geographical contexts (e.g. Asia and North America). Related to the previous point another limitation emerges: we know how many jobs have been moved away from Europe, but we are not aware about how many of these will be transferred to the destination country.

Finally, the ERM considers only corporate restructurings of a certain size. SMEs are worldwide dominant thus unmapped restructurings could be several. Even if in this case the dimension of the single relocation is likely not large, these relocations are likely to have unique characteristics with respect to those of large multinationals. It could be interesting to check which are the offshoring determinants of SMEs and compare them with those highlighted in our paper. Indeed, there are some studies showing that also small companies play an important role in offshoring and in general in internationalizing markets (e.g. Liesch and Knight, 1999; Oviatt and McDougall, 1994).

Abstract
Manufacturing reshoring is a booming topic in both research and practice. The existing literature is limited but rapidly growing. One area that is fairly covered are critical factors in a reshoring decision, commonly grouped within quality, cost, market and strategy. Within the cost category, hidden costs are a common problem. This problem arises due to lack of holistic view on cost factors. A comprehensive framework on cost factors for reshoring decisions is missing. The aim of this research is to identify critical cost factors to consider in a reshoring decision and structure them into a costing model.

Keywords: Reshoring, Manufacturing location decision, Cost factors

Introduction
Globalization has increased over the past two decades, and companies are facing increased competition from low-cost countries. In order to deal with this, companies in high-cost countries have moved parts of their manufacturing to the low-cost countries, termed as offshoring (Stentoft et al., 2016a). Over the years, rising wages and increased commodity prices have increased the cost of operating in these countries. Academics and consultants have concluded that offshoring was not inherently beneficial from a cost perspective, and have classified offshoring decisions as a ‘strategic mistake’ (Denning, 2013; Tate et al., 2014). This is due to the difficulties in estimating total cost due to too simplistic cost-based decision models (Brown, 2010).

As a correction measure, companies have taken decisions to repatriate manufacturing back to home country, termed as reshoring (Gray et al. 2013). There has been a large number of factors that has been addressed to drive reshoring. Many of them have been categorized into broader sets such as cost factors (Engström et al., 2018), quality factors (Stentoft et al., 2016a), market factors (Kinkel et al., 2012), risk factors (Tate et al., 2014) and supply chain factors (Ellram et al., 2013). From a manufacturing location decision point of view, an important category is costs. Often it occurs that the true costs of manufacturing location are not the same as calculated during the decision-making stage.

Manufacturing location decisions based on too few cost factors, lead to hidden costs that are unanticipated during the decision-making process and first discovered during the implementation process (Holweg et al., 2011; Larsen et al., 2013). Some of the hidden costs are related to complexity, coordination with the clients, language and cultural
barriers (Holweg et al., 2011; Larsen et al., 2013). These are not integrated in cost models, such as product costing - which is used to calculate the cost of the product. The cost of the product can be categorized from an activity point of view, into manufacturing cost, distribution cost, administration cost, and sales and marketing cost (Hundal, 1997). The cost categorization provides managers hierarchical relationship between the costs and distinguishes between expenses that are consumed on product level and those consumed on batch level (Cooper and Kaplan, 1991).

Several studies have focused on reshoring drivers and a holistic view on costs of reshoring have not yet been explored (Ancarani et al., 2015). Therefore, is a need to holistically study the costs that are involved in manufacturing reshoring decisions and integrate these costs into an existing costing model. The aim of this research is to identify critical cost factors to consider in a reshoring decision and structure them into a product costing model. The specific research questions are ‘1. What are the important cost factors that needs to be considered in a manufacturing reshoring decision?’, and ‘2. How can the cost factors be integrated into a product costing model?’. These questions will be answered through a systematic literature review.

**Methodology**

A systematic literature review is defined as “an explicit and a reproducible design” of collecting and analyzing the existing body of literature (Fink, 2019). The systematic literature review was chosen for few reasons. Firstly, a comprehensive view on the cost factors is missing from manufacturing reshoring decision perspective. Secondly, the application of a search algorithm improves the quality of the process and generates better results than traditional review processes. This is due to the clear definition, transparency and repeatability of the procedure (Seuring and Gold, 2012). Mayring’s process model (Mayring, 2000) is carried out, that consists of four distinct steps.

In the first step (material evaluation), the search was conducted in Scopus and Web of Science databases. These databases were chosen due to their overall size, scope and relevance in the field of international business. Only peer-reviewed academic journal paper in English language were selected since they have the highest impact in the given research. The search was conducted in the month of December 2018. No time delimitation was put since the interest in reshoring domain is only recently increasing (Wiesmann et al 2017; Barbieri et al., 2018). The main search terms and the search process are presented in Table 1. The final sample consists of 80 articles from years 2009-2018. The search for literature ended in December 2018, hence it includes a complete year.

</tbody>
</table>

In the second step (descriptive analysis), the descriptive analysis of the sample was performed. This analysis included aspects such as distribution of articles over the years,
In the third step (category selection), some predefined categories for the content analysis were selected. The categories were selected based on standard product costing models usually consisting of manufacturing cost, distribution cost, administration cost, as well as sales and marketing cost (Hundal, 1997). Costs that did not belong to the product costing were organized into a “other cost” category. The reason for the selection these categories is to provide managers with a hierarchical relationship between the costs (Cooper and Kaplan, 1991).

In the fourth and final step (material evaluation), the content analysis of the sample was performed based on the predefined categories. The entire research process is documented to ensure transparency and reproducibility of the research process.

**Descriptive analysis**

The distribution of articles across the timeframe along with a trendline is shown in Figure 1. The figure shows that literature on reshoring is exponentially increasing due to the growing academic interest in this area. The number of articles had peaked in the years 2014 and 2016 due to special issues on reshoring in prominent supply chain journals such as *Journal of Purchasing and Supply Management* and *Operations Management Research* respectively.

![Figure 1. Distribution of articles over the years (n = 80)](image)

The articles are spread over a number of different journals (Figure 2). Most of the journals are from operations and supply chain management area, due to the importance of reshoring from a supply chain perspective.

Within the sample, nine research methodologies have been identified: case studies, surveys, conceptual, secondary dataset research, modeling, literature reviews, experiment, Delphi and mixed methods (Figure 3). Majority of the papers have adopted case studies and surveys, in order to explore the reshoring phenomenon in its natural setting and increase the understanding of the context.

Within the sample, ten home countries were identified (Figure 4). The country with highest number of studies focuses on USA, followed by UK, western Europe and the Nordic countries. There has been only one study focusing on New Zealand.
Within the sample, the articles were mapped based on category selection. The graph shows the number of articles that address each of the cost categories from a reshoring point of view (Figure 5). The cost category that was addressed the highest is manufacturing cost, followed by total cost, distribution cost, administration cost and sales and marketing cost.
Content analysis
In total, 29 cost factors were found in the systematic literature review (Table 2). The cost factors were structured at four hierarchical levels.

Level 1 costs
On the first level, we have total cost and other costs. The total cost is the sum of all the costs involved in bringing a product to a market. Total cost is an important factor to consider since managers need to have a holistic view on financial and supply chain factors (Hartman et al., 2017). The other costs consist of project costs.

Level 2 costs
On the second level the total cost is further divided into manufacturing costs, distribution costs, administration costs and sales and distribution costs. The manufacturing cost is the cost of manufacturing a product over a given period. Manufacturing cost calculations have evolved from high component of labor costs to high component of overhead costs (Abbasi et al., 2016). The distribution cost is the cost of physically distributing the product. Some papers also use the term logistics cost that also concerns the cost of physically distributing the product (Ancarani et al., 2015; Tate et al., 2014). The increase in distribution costs is due to higher transportation costs in global supply chains (Tate et al., 2014; Wu et al., 2014). The administration cost is the cost of running an organization. The increase in administration cost is due to higher costs of maintaining foreign operations and relationships and excessive paperwork (Fratocchi et al., 2016; Moradlou and Backhouse, 2017). Higher administration costs are associated with “captive” type of reshoring, when ownership is retained (Heikkilä et al., 2018b). The sales and marketing cost include the cost of advertising and marketing-related activities. The increase in sales and marketing cost is due to companies’ investment on marketing-related activities in the offshoring country (Pearce, 2014). Also, for marketing-intensive companies, the marketing costs should be taken into consideration to avoid “unpleasant surprises” to managers (Kinkel, 2009).

On the second level, the other costs are divided into switching costs and product redesign costs. Switching costs is the cost of relocating operations (to the home country). High switching costs can prevent reshoring of certain product lines (Gray et al., 2017). Product re-design cost is the cost of redesigning or developing a product. High investments in R&D and re-design is a crucial factor for location decision (Kinkel and Maloca, 2009).

</table>

**Level 3 costs**

On the third level, the manufacturing costs are further divided into direct material cost, direct labor cost and factory cost. The direct material cost are those material costs that are...
directly involved in making the product such as raw material costs or component prices (Engström et al., 2018; Fratocchi et al., 2016; Tate et al., 2014). The direct labor cost are those labor costs that are directly involved in making the product. Majority of reshoring cases have been a counter move to increasing labor costs (Zhai et al., 2016). Labor costs is a significant reason for reshoring decisions (Johansson and Olhager, 2018a; 2018b). The factory costs are those costs that are required to run the factory. They represent fixed costs or manufacturing overheads (Vanchan et al., 2018). These are further broken down under level 4.

On the third level, the distribution costs are further divided into warehousing cost, inventory holding cost in distribution centers, transportation cost, customs cost, order fulfillment cost, stockout cost (lost sales) and late deliveries cost. Warehousing cost is the cost of handling the product in the warehouse, including packaging prior to shipping. Higher than expected warehousing costs have reduced the benefits of offshoring (Gray et al., 2017). Inventory holding cost is the cost of holding the inventory at the distribution center. This increases when capital is tied up on slow steaming boats (Tate et al., 2014). Transportation cost is the cost of physical movement of goods. Increasing transportation cost have reduced the benefits of offshoring (Barbieri et al., 2018; Wiesmann et al., 2017). Customs cost is the cost of customs and duties that are paid for export or import. Changes in customs costs can reduce the attractiveness of offshoring (Benstead et al., 2017). Order fulfillment cost is the cost of fulfilling an order. Higher cost of fulfilling order can reduce the attractiveness of the offshoring market (Ocicka, 2016). Stockout costs are the cost when the lost sales due to out-of-stock products. Late deliveries cost is the penalty that is paid for late deliveries. Long customer lead times can increase the stockouts, late deliveries and lost sales (Fratocchi et al., 2016; Yu and Kim, 2018).

On the third level, the administration costs are further divided into coordination cost, monitoring cost, non-compliance cost, and legal cost. Coordination costs are the costs of coordinating different locations and this cost increases when manufacturing is located in different regions (Ancarani et al., 2015). Monitoring costs is the cost of monitoring the operations of business. Monitoring costs can also include the cost of auditing operations and personnel (Gray et al., 2017; Robinson and Hseih, 2016). Another part of administration cost is the cost of non-compliance. This cost is occurred when a firm fails to comply with local regulations. The last part of administration cost in the framework is legal costs. In one of the case companies, complicated and bureaucratic legal system increased costs of legal counselling and tax lawyers (Engström et al., 2018).

Level 4 costs
On the fourth level, the factory costs are divided into indirect labor cost, indirect material cost, energy cost, inventory holding cost at the factory, quality deficiency cost, land cost, facility cost, equipment cost. The indirect labor costs are those labor costs that are not directly involved in making the product. These costs include the salaries of management and supervision of the factory (Vanchan et al., 2018). The indirect material costs are those cost that are not directly go into the product. These costs are incurred in maintaining machines and buildings (Vanchan et al., 2018). The energy cost is the cost of energy at a location. Cheaper energy costs have caused reshoring in the USA, in contrast to UK where the energy costs are much expensive (Bailey and De Propris, 2014a). The inventory holding cost is the cost of holding the inventory at the factory. Streamlining the flow in production processes can reduce the cost of holding inventory at the factory (Bals et al., 2016). The quality monitoring cost is the cost of controlling the quality through inspection. High quality monitoring costs were incurred in order to keep the quality standards in the offshore location (Bals et al., 2016; Gray et al., 2017). The land, facility
and equipment costs are the cost of land, facility and equipment at the manufacturing location respectively. In a Swedish case study on reshoring, investments had to be made in new facility to reshore a product (Engström et al., 2018).

Concluding discussion

Many location decisions have been taken without a complete view on the cost factors, leading to “hidden costs” in the supply chains. This is also supported by Ellram et al., (2013, p. 19) that “developing a comprehensive risk assessment analysis and a total cost of doing business in a particular region will help organizations make the appropriate decision”. The focus of this study has been to uncover the cost factors that need to be considered in manufacturing reshoring decisions. In total, 29 cost factors were found in the systematic literature review with sample size that is larger than previous literature reviews on reshoring (e.g. Barbieri et al., 2018). The cost factors were structured at four hierarchical levels. The structure of the cost factors provides a holistic view on the costs that need to be considered in manufacturing reshoring decisions. This can serve as a checklist and help managers identify those cost factors that influence the reshoring decision. Moreover, understanding the costing structure can provide insights to create decision models. It should be noted that reshoring decisions are influenced by strategic factors as well and basing these decisions purely on cost is not recommended. However, understanding the hierarchical levels of costs can help create more complete decisions models.

For future research, the decision-making process is still of high priority (Bals et al., 2016; Barbieri et al., 2018). Recently, intelligent techniques of decision making have been demonstrated in the reshoring domain (Hilletofth et al., 2019). Hence, it would be useful to implement such intelligent techniques to model reshoring decisions using the costing framework. Also, it would be interesting to perform empirical studies that focuses on the framework of cost factors of reshoring, particularly in-depth case studies. Another avenue of future research would be to study the extent to which the cost factors impact on the reshoring decision. Within the framework, it would be meaningful to explore the sales and marketing costs and other costs that affect manufacturing reshoring decision.

Abstract

The reshoring phenomenon has gained momentum among managers, scholars and policy makers. Literature has mainly focused on reshoring motivations/drivers, locations, and activities. Only a few papers have studied its performance impact and they are characterized by significant limitations. Our study seeks therefore to present the first systematic analysis on the impact of reshoring on operational performance based on balance sheet data. Our analyses show that reshoring does not allow a better profitability, nor an increase in sales or in labour productivity. It seems however to allow an improvement in operating margins thanks to the increase in value per unit.

Keywords: Reshoring, Backshoring, Firm performance

Introduction

In the last decades an increasing number of companies have decided to reshore – i.e., bring back home – their manufacturing activities (Fratocchi et al., 2016). In the US, reshoring has achieved a high level of popularity since the jobs created in 2016 by reshoring and foreign direct invest surpassed those exported by offshoring (Reshoring Initiative, 2016). The reshoring phenomenon has gained momentum also among policy makers and scholars (Barbieri et al., 2018).

Despite the number of open questions that arise about the performance impact of reshoring, only few papers have dealt with this issue (Brandon-Jones et al., 2017; Johansson and Olhager; 2018; Stentoft et al., 2018). These studies are however characterized by significant limitations concerning both the performance measures considered and the methodological approaches (see “background and research framework” section for further details). As a consequence, the impact of reshoring on firm performance is far from clear.

Based on secondary data from the Bureau van Dijk’s Orbis database, which contains balance sheet information on over 250 million companies worldwide, and the Uni-CLUB MoRe back-reshoring database, which contains data about more than 700 reshoring cases drawn from a
wide range of sources (e.g., newspapers/magazines and white papers from consulting firms), this paper tries to fill the above-mentioned gap.

Our evidences suggest that reshoring does not allow a better profitability of assets, an increase in sales, or even an increase in labour productivity. On the contrary, reshoring seems to allow an improvement in operating margins thanks to the increase in value per unit. Therefore, the reshoring choices analysed in this study seem to support consolidation or repositioning strategies in market segments associated with premium prices. The qualitative analyses carried out on a sample of some cases seems to confirm this interpretation.

**Background and research framework**

An increasing number of papers have focused on the reshoring topic. As pointed out by some recent systematic literature reviews (Barbieri et al., 2018; Wiesmann et al., 2017), reshoring literature has mainly focused on reshoring motivations/drivers, locations, and activities (Barbieri et al., 2018). Reshoring has been seen both as a correction of a managerial mistake (Gray et al., 2013; Kinkel and Maloca, 2009) and as a strategic decision to face exogenous or endogenous changes (Fratocchi et al., 2015; Gylling et al., 2015; Martínez-Mora and Merino, 2014). A wide set of specific motivations have been highlighted and classified in various ways (e.g., Foerstl et al., 2016; Stentoft et al., 2016; Fratocchi et al., 2016; Srai and Ané, 2016). Stentoft et al. (2016) highlighted for instance the following categories of reshoring motivations: cost, quality, time and flexibility, access to skills and knowledge, risks, market and other factors. Similarly, Wiesmann et al. (2017) identified five categories of reshoring drivers and barriers: global competitive dynamics, host country, home country, supply chain (cultural or physical distance), and firm-specific motivations. Fratocchi et al. (2016) proposed instead a theory-driven classification framework based on two dimensions: the firm’s strategic goal (increasing customer perceived value vs. improving cost-efficiency) and the level of analysis (internal to the company vs. related to the external environment). Reshoring appears therefore aimed at improving one or more internal performance, such as costs, delivery times and reliability, quality. However, is such an internal performance improvement achieved through reshoring? And does it positively affect economic-financial performance (e.g., sales, productivity, profitability)?

There are only a few papers on the impact of reshoring on firm performance. Brandon-Jones et al. (2017) analysed the impact of 37 reshoring decisions announced by US firms on shareholder wealth. Johansson and Olhager (2018) shed light on the relationship between offshoring and reshoring motivations and the performance outcomes. Stentoft et al. (2018) showed that reshoring has a negative effect on delivery lead time and no effect on cost performance and cost accounting capabilities. These studies are however characterized by a set of significant limitations. The study of Brandon-Jones et al. (2017) is based on a small sample and consider a specific performance measure (stock returns) which might not reflect the economic and financial performance of the firm; the other two papers are instead focused on a single country (i.e., Sweden and Denmark) and use perceptual performance measures. The impact of reshoring on firm performance is therefore far from clear.

Based on previous reshoring literature we develop below a set of hypotheses on the impact of reshoring on various economic-financial performances.

Previous reshoring research (e.g., Fratocchi et al., 2016, Kinkel et al., 2014) showed that most of reshoring cases are from South-East Asia and Eastern Europe to Western Europe and USA. Labour productivity is in general significantly higher in the Western World. Evidence of this can be found in macro-economic data. Even if productivity of Chinese workers has increased in the last years (+9.5%/year on average in 2007-2012, +7.3%/year in 2012-2013 and +7% in 2014, Nofri, 2015), in 2015 each employed worker in China generated only 19% of the amount of GDP produced by an American worker (Schuman, 2017). We can therefore hypothesize that:
H1: There is a significant positive relationship between reshoring and labor productivity. Various reshoring motivations – such as “made-in” effect, improving delivery reliability, improving quality – could have a positive effect on the relationship with customers and more in general with the brand image (Di Mauro et al., 2018). We can therefore hypothesize that:

H2: There is a significant positive relationship between reshoring and sales growth.

On the one hand, previous studies included among possible reshoring motivations the labour costs (which raised significantly in emerging countries in the last years), the logistic costs, and the total cost of ownerships. On the other hand, some studies argued that reshoring could allow companies to charge premium prices thanks to the made-in effect or the better brand image. We can therefore hypothesize that:

H3: There is a significant positive relationship between reshoring and Gross Profit percentage.

Finally, considering the potential positive effect of reshoring both on sales and on costs, we can hypothesise that:

H3: There is a positive relationship between SA8000 adoption and profitability.

Methodology and data

This study is based on secondary data from the Bureau van Dijk’s Orbis database, which contains balance sheet information on over 250 million companies worldwide, and the UniCLUB MoRe back-reshoring database, which contains data about more than 700 reshoring cases drawn from a wide range of sources (e.g., newspapers/magazines and white papers from consulting firms). From the matching of the two databases, we obtained a sample of 160 firms, whose year of reshoring, country of origin and Standard Industry Classification (SIC) code is showed in Table 1 and 2.

We employed the event-study methodology to detect abnormal performances between the 160 reshoring firms and a wide set of control firms, following the procedure proposed by Barber and Lyon (1996).

The event study is a statistical methodology used to assess the impact of an event on the firm, and specifically, it evaluates if there has been an abnormal performance following the event by analyzing the performance that there would have been without the event and comparing it to the performance that has actually been measured. To calculate the abnormal performance, we use the formula:

\[
AP_{(t+b)} = PS_{(t+b)} - EP_{(t+b)}
\]

\[
EP_{(t+b)} = PS_{(t+a)} + (PC_{(t+b)} - PC_{(t+a)})
\]

Where AP is the Abnormal Performance, EP is the Expected Performance, PS is the actual performance of the sample firm, and PC is the median performance of the control firms. The subscripts regard the time period considered. The t is the reshoring year, b is the ending year of comparison (which can be -1, 0, 1, 2, 3) and a is the starting year of comparison (which can be -2, -1, 0, 1, 2).

The statistical analyses used to determine if the abnormal performance is significantly different from zero are the t-test (parametric), which is well specified for symmetric and normal distributed data and the Wilcoxon Signed Rank test (non-parametric), which has less stringent requirements. To check the validity of the p values obtained, the Benjamini-Hochberg procedure has been employed with a false discovery rate of 10% and 5%. In this way, we should
get rid of type I error in null hypothesis testing, which occurs when there is a rejection of the null hypothesis when the null hypothesis is true.

The following steps were adopted to find the sample of control firms to calculate the expected and abnormal performance. The procedure consisted in finding, for each of the 160 firms in the sample, other firms which are similar in terms of size (total assets in the last available year), industry and performance measure in the year considered, that is the reshoring year (t) minus one, which we considered the pre-event year. As Barber and Lyon (1996) state, tests statistics are well specified only when sample firms are matched to control firms with similar pre-event performance. In fact, performance matching adjusts for the mean reversion in accounting data that reflects a transitory component of operating income, component which can confound analyses. More specifically, matching the firm’s performance will allow researchers to avoid evaluation mistakes that derive from wrong conclusions about the performance development. In fact, if a firm performs very well or very poorly in a certain period of time, it is supposed that its performance will stabilize to a more “normal” level after a while. The steps we followed to select the firms of the control sample to evaluate the expected performance are taken from the Barber and Lyon procedure and are:

- Step 1: find companies with at least two-digits SIC code, 50-200% of firms’ total assets and 90-110% of the considered performance in the year t-1.
- Step 2: If no not-reshored companies were matched in step 1, use at least a one-digit SIC code, 50-200% of firms’ total assets and 90-110% of the considered performance in the year t-1.
- Step 3: If no not-reshored companies were matched in step 2, use 50-200% of firms’ total assets and 90-110% of the considered performance in the year t-1.

Once these companies were found, companies that ever did reshoring were removed from the control sample and then the median of the performance considered was calculated in the time window considered for the event study, which is from year t-1 to year t+3, where t is the reshoring year.

In selecting the control firms, we deleted firms that had not available data from year t-1 to t+2, with the exception of companies that did reshoring in year 2015, for which we did not apply this rule for the year t+2 (2017) and for companies that did reshoring in year 2014, for which we did not apply the rule in the year t+3 (2017), because of the scarcity of performance information available in that year.

We used the main performance measures adopted by previous event studies (e.g., Orzes et al., 2017; De Jong et al., 2014; Lo et al., 2014): ROA (EBIT/Total Assets), Gross Profit Margin (Operating Revenues – Cost of Goods Sold)/Operating Revenues), labour productivity (EBIT/Number of Employees), and the relative sales growth ((SALESt – SALESt-1)/SALESt-1). We then defined the event period as the year in which the reshoring decision was implemented or announced (year t) and identified for each reshoring firm a portfolio of non-reshoring control firms using the following criteria: (1) the same two-digit SIC code; (2) 50-200% of firms’ total assets; and (3) 90-110% of the considered performance in year t-1.

We finally estimated the abnormal changes in performances of the sampled firms in comparison with the control firms and tested whether they differed significantly from zero.
Results
Table 3 shows the descriptive analyses of the sampled firms in the year t-1.

Tables 4a-4d presents the results of the event study, distinguishing three main time periods: pre, i.e., before reshoring (t-1 to t); post, i.e., after reshoring (t to t+3); and full (t-1 to t+3), and a control period (t-2 to t-1) to tackle the endogeneity issue.

Our analyses show a general decrease of labor productivity in the years after the reshoring decision (Table 4a). There is in particular a significant negative abnormal performance in the full period (from year t-1 to t+3). The result is significant also after the Benjamini-Hochberg correction for the Wilcoxon Signed-Rank test with a False Discovery Rate of 10%. As a consequence, hypothesis H1 should be rejected.

We find then no evidence of increase (nor of decrease) of sales in the periods considered (Table 4b). Hypothesis H2 should therefore be rejected.

As far as Gross Profit percentage is concerned, we find an increase in the post (from year t to t+3) and especially in the full period (from year t-1 to year t+3) (Table 4c). The test of the full period is significant also after the Benjamini-Hochberg correction with a false discovery rate of 10% for the t test and the WSR test and of 5% for the t test. Given these results, H3 can be accepted since there is a significant positive relationship between reshoring and Gross profit percentage.

Finally, there is a slight significance of a decrease in ROA (AP mean of -1.076) in the year prior to reshoring (from t-1 to t) (Table 4d). This result is anyway not significant if we apply the Benjamini-Hochberg procedure with a false discovery rate of 10% or 5%. Hypothesis H4 should therefore be rejected.

In conclusion, H1, H2, and H4 should be rejected since reshoring does not seem to lead to improvement of labor productivity, sales performances, or profitability. H2 can instead be accepted since we found a positive effect of reshoring on Gross Profit percentage.

*p<0.1, * p<0.05, ** p<0.001. The p-values shown are those for the one-sided test of the null hypothesis of no abnormal performance, using a t-test and a Wilcoxon signed rank test, respectively. Given that the hypothesis of normally distributed abnormal performance was rejected in most cases by the Shapiro-Wilk test at the 1% level, the t test is not very appropriate; but reported for the sake of completeness.

The p values are corrected with the Benjamini-Hochberg procedure with a False Discovery Rate of 10% and of 5%.

Discussion

Labor productivity results show a significant decrease in the full period, against hypothesis 1. This may be due to the decreased EBIT or to an increase in the number of employees, which may result from the relocation of activities back home. In fact, when relocating with an insourcing mode, firms might have to hire new employees, and these should be trained for a certain period to reach the desired level of productivity. Another reason for this result could be that labor productivity in Asian countries continued to improve in the last years, reaching closer levels to the Americans and Europeans. Furthermore, the availability of skilled labor may have been deteriorating (Porter and Rivkin, 2012).

We then do not find any effect of reshoring on Sales Growth. This is quite surprising considering that many reshoring motivations highlighted by previous reshoring literature are potentially related to sales, such as made-in effect, quality, and delivery reliability. In order to be better understood, this result should be considered together with the other performances.

Our analyses show a positive effect of reshoring on Gross Profit Margin, for which we accept hypothesis H3. Gross Profit Margin, which is equal to (Operating Revenues − Cost of Goods Sold)/ Operating Revenues, can be expressed as follows: ([unit price *sales volumes − unit cost*sales volumes])/(unit price *sales volumes). Considering that unit price * sales volumes
does not change, since there is no difference in the relative sales growth, we can argue that increase in Profit Margin is due to a reduction in unit cost*sales volumes, which may be due either to (1) a reduction in unit cost or to (2) a reduction in sales volumes (associated with an increase in unit price since unit price*sales volumes should be constant). While hypothesis 1 seemed to be less likely than hypothesis 2, since usually companies reshore to higher-cost countries (Fratocchi et al., 2016), we qualitatively analysed a set of cases from the dataset (by reading the case descriptions/narratives and/or the media sources) to better explain our results. In many cases, we noticed that reshoring seems associated with a strategic choice of repositioning towards high-end segments, characterized by premium prices.

Finally, the decreased ROA in the years before the reshoring may be due to an increase of the total assets in view of this transfer. In fact, when firms relocate production at home from an outside location, they could invest on facilities or machinery for production. This depends from the relocation mode that the ownership re-rentry mode (outsourcing vs insourcing) and by the volumes. In the sample, the proportion of firms that did reshoring with an insourcing mode is 83.7% (134/160 firms). This considerable amount could explain this ROA trend. The big incidence of firms that employ reshoring and insourcing together is also confirmed by the research of Bals et al. (2016). As we stated in the hypothesis, if the majority of firms would have employed the outsourcing reshoring mode, probably the impact on ROA would have been demonstrated to be more significative. Another reason for the lack of significant results may be that the portion of production reshored is too small to highlight a significative impact.

**Limitations**

The study presents some limitations that should be taken into account. First of all, we have no information about the percentage of reshored activities on the total. Reshoring regards sometimes just a limited part of the production in a company. In the case of partial reshoring, we expect that the initiative cannot have a significant impact on performances. Another limitation of the research regards the sample composition: it mainly consists of large companies (80.6% of the sample). We expect that the reshoring impact on the latter ones could be much more significative and could affect the results of this kind of mixed sample.

Another limitation concerns possible joint effects: the sampled firms could have other projects implemented when reshoring (for example renovations, collaborations, FDI decisions etc.) and this could have an influence on the performance. Moreover, a relevant part of the sampled firms did reshoring in the years from 2006 to 2013, which is the period of the economic crisis. This event could influence the results since that was a period of depression and decline. We don’t consider these aspects and therefore the results obtained may not be directly linked only to reshoring.

**Directions for future research**

An interesting development could be the analysis of a new sample of firms in more recent years in the post-crisis. It could be interesting to estimate the impact on performances of the tax reform of the President Trump has come into force and that the government incentives are more pronounced. Future analyses should also be more focused on assessing some categories, for example taking into consideration only small and medium firms or only large firms, e.g. comparing US or Europe. Another future investigation to be done is to understand if there has been an impact on the costs and, to be more specific, a reduction in the cost of goods sold. In our analysis, in fact, this result is not very clear and therefore the employment of more efficient measures to assess the impact on performance, such as the evaluation of the voice of the balance sheet “cost of goods sold”, could be employed. However, to have more reliable results it is essential that the entity of production reshored is known (e.g. a single component, the total
production or a percentage of the production), so that a more precise and focused analysis can be made.

Abstract

This study aims to develop a framework for reshoring case study research, specifying the aspects encompassing a full case description. The meta-synthesis methodology was applied on a sample of 14 articles including 36 cases of offshoring and subsequent reshoring activities. By focusing on findings by the original authors, the study allowed to build a comprehensive framework to lead future case study research, and accumulate knowledge by using a methodology never applied to this field. In doing so, the article contributes to reshoring research. Furthermore, the study generates practical implications, by condensing all the evidences about reshoring in one single study.

Keywords: Manufacturing relocation, Offshoring, Backshoring, Meta-synthesis

Introduction

Reshoring of manufacturing as a means for international firms to optimize their global manufacturing footprints has gained increasing attention in academia. It is a relatively new research stream that has primarily been studied conceptually. For example, a number of frameworks describing the reshoring process are presented in previous literature. These typically only cover relocation in one direction, i.e. offshoring (Mihalache and Mihalache, 2016) or reshoring (Bals et al., 2016; Benstead et al., 2017; Foerstl et al., 2016), or consider reshoring as one of several possible subsequent relocation alternatives to offshoring (Joubioux and Vanpoucke, 2016). However, it is now widely acknowledged that reshoring cannot be pursued unless there has been previous offshoring (Gray et al., 2013). Accordingly, there is a need to take a broader perspective and study reshoring in relation to the previous offshoring decision in order to understand the complex dynamics behind a firm’s internationalization process. Thus, it is timely to develop a reshoring framework that includes all elements needed for a full understanding of the reshoring process. Several case studies have been performed to gain a deeper understanding of why and how location decisions are made. These have made substantial contributions, but there has been little accumulation of the knowledge gained from these studies. This has
important implications for knowledge development, because the rich findings from case studies can reach disparate conclusions, and the knowledge produced tend to remain isolated, stand-alone works. The meta-synthesis methodology has thus been developed with the purpose to aid the evolution of knowledge in management studies, by revisiting the findings of other researchers and discovering rich complexities and insightful nuances that cannot be obtained from individual case studies (Hoon, 2013).

The purpose of this study is thus twofold. Following the suggestion by Benstead et al. (2017), we first aim to develop a framework for reshoring case study research, specifying the aspects encompassing a full case description. Second, we will use the meta-synthesis methodology to analyze existing reshoring case research, with the aim to refine the framework and advance the knowledge within the field. Thus, we review 14 articles with 36 cases of offshoring and subsequent reshoring events. The unit of analysis in this study is the two connected events, i.e. reshoring and previous offshoring, with offshoring being considered as an antecedent to reshoring. The novelty of this research is that we include both offshoring and subsequent reshoring operations in a conceptual framework for reshoring case research. In addition, we conduct a meta-synthesis, which is a methodology that has not yet been applied within this field.

Related literature

Offshoring has been referred to as “the assignment of business activities to locations outside a firm’s national borders in order to support existing business operations” (Mihalache and Mihalache, 2016; p. 1105), thus highlighting that the offshoring decision is considered to be a rational choice based on the assumption that a host country provides a comparative advantage with respect to the home country. As such, the offshoring decision is far from being irreversible. As a consequence, a new phenomenon, which entails the reverse movement from the offshore location to the home country, has started to spread in the last decades. Interestingly, both academia and practice have struggled to find the right terminology, as well as to set the boundaries for this phenomenon (Foerstl et al., 2016; Wiesmann et al., 2017). In this paper, we will use the term “reshoring”, given that it is the most widespread among recent studies, and we define it as “a voluntary corporate strategy regarding the home country’s partial or total re-location of (in-sourced or out-sourced) production to serve the local, regional or global demands” (Fratocchi et al., 2014; p. 56).

As a starting point for this study, we reviewed frameworks from existing literature, summarized in Table 1.

</table>
In particular, we noticed that the frameworks developed in the reshoring field are relatively recent, given that they started to appear in 2016. Interestingly, they all focused on different and concurrent aspects of reshoring. Bals et al. (2016) developed a framework focused on the reshoring decision-making and implementation process, while Foerstl et al. (2016) presented a framework pinpointing the relationship between drivers and outcomes and the moderating role of contingencies. Fratocchi et al. (2016) developed a theory-based framework of reshoring drivers, dividing them into four quadrants depending on if they are either internal or external and oriented either towards cost efficiency or customer perceived value. Joubioux and Vanpoucke (2016) developed and empirically refined the only framework encompassing both offshoring and reshoring, thus supporting the relevance of studying the two phenomena together. Finally, Benstead et al. (2017) highlight the relevance of contingencies in their framework, by assuming that both drivers and implementation considerations change according to multiple contingent factors. They develop an empirically refined framework that start to show comprehensiveness towards the main aspects that need to be considered by a reshoring company.

Framework development
In order to guide the research process, we developed an initial conceptual framework by integrating the elements considered in previous literature, see Table 1. Most of the frameworks focus on the decision-making process and the drivers, but the implementation process (Bals et al., 2016; Benstead et al., 2017), contingencies (Benstead et al., 2017; Foerstl et al., 2016) and outcomes (Foerstl et al., 2016) are also acknowledged as important aspects. Thus, we incorporate all identified aspects to provide a complete framework. We give offshoring and reshoring equal importance, in order to understand their relationship and thereby fully understand the reshoring decision. As a starting point, we used the framework developed by Benstead et al. (2017), which we consider to be the most complete and intuitively accessible framework of the reshoring process in existing literature. The framework is depicted in Figure 1.
Methodology
This study follows the meta-synthesis methodology developed by Hoon (2013), which is an exploratory, inductive methodology aimed to make contributions beyond those presented in original primary qualitative case studies (Hoon, 2013). It has been described as an “analysis of the analyses”, as it focuses on the insights and interpretations of the original authors, rather than on the firsthand data about the specific cases.

First, we located the relevant research by developing a search strategy for case study research on the reshoring phenomenon, including descriptions of the preceding offshoring process. We used the search terms “reshoring” and “case study”, and related terms (reported in Figure 2), as identified in previous literature. The potentially relevant literature was retrieved from Scopus and Web of Science since we focused on peer-reviewed sources with strong academic contributions that are relevant to synthesize, and not merely providing illustrative examples of manufacturing relocation. The initial sample consisted of 365 articles. Here, we applied a set of clearly specified inclusion and exclusion criteria in order to ensure a high validity of the synthesis. Particularly, we only included articles from peer-reviewed sources that used case-based methodologies, including both offshoring and subsequent reshoring decisions of manufacturing activities in specific. After initial reading and preliminary coding of the articles, a number of articles were excluded since they did not report enough information to be analyzed. Thus, the final synthesis sample includes 14 articles and 36 cases. Figure 2 summarizes the full literature search process. Second, we coded the article content following the suggestions by Durach et al. (2017). Thus, we developed a coding scheme in two levels; (i) first according to the ontological and epistemological study artifacts, and then (ii) following the aspects in our framework. The coding and analysis were done iteratively in two phases, following the recommendations by Hoon (2013). First, we made an initial coding scheme based on the initial framework. After the first round of coding of the articles, we refined the framework based on the articles evidence. Then, we conducted a second round of coding using an updated coding scheme following the final framework. To keep track of the coding process and to support the data analysis we used the software NVivo Plus 12. In order to avoid any potential bias along the process, two researchers were involved in all the phases and results were discussed after each phase with experienced researchers knowledgeable within the field.

![Figure 2 - Literature search process](image-url)
Results
Case study research on reshoring is in its early stages. All studies found in our literature review could be considered recent, with the first publication in 2014 following an increasing number of publications each year. The articles are mainly published in OM or SCM journals. Concerning geography, the studied articles are mainly conducted from a European perspective, with only one study conducted outside of Europe (i.e., in the US). In terms of host countries, firms have moved activities to multiple locations, mainly to China or India but also Eastern European countries. Table 2 presents the sample articles.

According to Durach et al. (2017), studies within SCM normally use a range of different ontological and epistemological artifacts. Accordingly, we analyzed the sample articles to understand if we needed to apply a specific contextual lens when comparing results. The studied articles do indeed use a plethora of theoretical perspectives. Five studies mention several theories related to resourcing or manufacturing relocation in general, but they do not explicitly take a stand and use either of these theories. Three studies do not mention any theoretical perspective, but only discuss the results of previous offshoring and resourcing studies. Interestingly, the remaining studies use different theoretical perspectives. This indicates that there is no dominant or generally accepted theory for resourcing, which allows us to analyze the results without applying a specific lens. Further, the unit of analysis was not clearly mentioned in as much as 50% of the articles. However, the perceived unit of analysis in these cases was the firm. Thus, in ten studies the unit of analysis was the firm, while the decision was used in two articles, and intra-firm network and external network were studied in one article respectively. The majority of studies (86%) only collected data from one entity in the supply chain and used multiple respondents. In general, data had been collected at the top management level. The majority of the studied articles use the term resourcing, defined as the activity of moving manufacturing activities back to the home country or original location, regardless of ownership mode (alternatively not mentioning the ownership mode). Six studies use different terms, but their definition is similar to resourcing, with just a stronger emphasis on the ownership mode in the sense that some studies mention insourcing specifically (i.e., the activities are re-integrated with the domestic activities internal to the firm). Most studies are multiple case studies, with number of cases varying between two and 14 (the
average number of cases is 5.1). Five studies are single case studies. Two studies are mixed method studies, using both case study methodology and survey data or simulation. As could be expected, the amount of information provided about the cases differ significantly between the papers depending on number of cases included. In general, single case studies are richer and provide more information. The studied firms are operating within a variety of industries, from clothing, textile and shoe manufacturing to construction, automobile, aeronautics and maritime industries. In terms of firm size, all sizes are represented. We can thus conclude that offshoring and reshoring are occurring in a variety of industries and they are not limited to certain firm sizes. Investigating the offshoring and reshoring time span, it is clear that the majority of studies are represented by firms that have operated offshore for more than ten years. Only one study represents a shorter time span, where the offshoring was made during 2007 and 2008 and activities were repatriated in 2010. Quite surprisingly, four out of fourteen studies did not mention the time period for offshoring and reshoring at all.

The second level coding scheme was applied on the analyses of the original authors, i.e. the results, discussion and conclusions sections of the studied articles. First, we analyzed which elements were discussed by the original authors for each article, showing that all the elements in the framework have been discussed by at least one article in our sample. Thus, we conclude that the coding scheme is complete, and the framework sufficiently covers everything that is reported in our studied articles. Second, given that we allowed to code the same sentence in a specific article with multiple codes, we assessed the cross-coding (i.e. how often two codes appeared together). The coding similarity was checked with a Sørensen’s similarity metric, as displayed in Figure 3, which clearly highlights which codes are discussed together in our sample articles.

![Figure 3 - Codes clustering by coding similarity](image)

The analysis allowed to easily find relationships among the framework elements. The lines indicate associations among codes characterized by Sørensen’s coefficient ranging
between 0.8 and 1. In line with the current debate on reshoring, an interesting result is related to the comparison between offshoring and reshoring motivations. From Figure 3, it is easy to notice that the offshoring decision is strongly connected to domestic internal (e.g. firm strategy, efficiency, cost reduction), supply chain (e.g. relationship with suppliers, commercial agreements) and global external factors (e.g. differences in labor costs). The reshoring decision instead is related to a wider set of motivations, given that the similarity is high with all the factors. Another interesting result is the time/dynamic element that is strongly connected to both the offshoring and reshoring decisions, thus confirming that such strategic decisions require a time-consuming process. Moreover, the connections with all the factors indicate how these elements might evolve over time while the companies are making decisions, as well as while they are operating offshore.

Discussion and framework refinement
Based on the results of the coding, we refined the conceptual framework as depicted in Figure 4. The framework is structured in a way that makes it intuitively easy to follow, guiding the data collection for a full case description in case study research. Time, and the dynamic nature of manufacturing relocations, emerged as an important factor in the analysis. Therefore, the horizontal axis in the framework is illustrating time, while the domestic and offshore operations are depicted on the vertical axis. Influencing factors (i.e. drivers and barriers) can be found in the middle and are related to both offshoring and reshoring. Their categorization is inspired by Wiesmann et al. (2017), but the terms are adapted to fit our framework, using the differentiation between internal and external as suggested by Fratocchi et al. (2016). Below, each aspect of the framework is discussed together with illustrations from the studied papers.

**Figure 4 – Refined conceptual framework of the offshoring and reshoring processes**
**Decision-making**

Decision-making is related to aspects included in the decision, such as the specific product and activities to be relocated, the location decision, and the decision-making process, in terms of phases and people involved. It also includes the motivations of the offshoring or reshoring. In the final framework we avoided to refer to these elements as drivers or barriers. Instead, we prefer to use the term factor, thereby acknowledging that they can change over time and turn from drivers to barriers and vice versa. Several of our reviewed papers specifically focused on the reshoring decision-making, and the drivers and barriers in particular (papers A, B, C, F, G, J, and K from Table 2). Only paper G studied the actual decision-making process, from a heuristic decision-making perspective. As part of the decision-making, firms need to make a risk assessment related to the new location. For offshoring, financial risk and quality issues are considered the main threats (paper C). For reshoring, the risk of lost know how and access to knowledge needs to be assessed (both within the firm and in the local network), as this could possibly reduce the possibilities to repatriate manufacturing and thus act as a major barrier for reshoring (papers C, H, and I). As part of the drivers, we specifically distinguish the tipping point, as it emerged as relevant in several of the studied articles. For offshoring, the tipping points mentioned were requirement from a key customer (paper I) and bad profitability at the domestic site (paper B). For reshoring, negative events at the offshore site (e.g. quality issues or IP violation) (papers F and G), diminished cost differentials (paper B and F), free capacity at the domestic site (paper M), and a new business model (paper D) triggered the decision. In all of these cases the firms had more than one reason to relocate manufacturing. But each of these reasons were not important enough to drive the decision. Instead, the issues were building up and the firms had to reach a tipping point when one driver made the current situation unsustainable, leading to the decision to repatriate. As part of the decision-making, we also include the product as well as the specific activities to be relocated. Interestingly, paper J finds that the product seems to be interrelated with the location decision for the offshore activities. The activities that are offshored are mainly considered as non-core (papers A, C, H, and N). For reshoring, activities are fine sliced, which means that firms are reshoring very specific activities that fit within the current activities at home. In fact, reshoring was in many cases made partially.

**Implementation**

The implementation process of reshoring has been highly unexplored, according to Bals et al. (2016). Of our reviewed articles, only paper F explicitly studied how the reshoring implementation can be operationalized. Thus, we included their aspects such as governance mode, degree of relocation, incremental or instantaneous process, maintaining production at the domestic site, information sharing, and preparation activities. Several studies in our sample reported on aspects related to the implementation process, even if they did not explicitly study it. For example, it becomes evident from the studied papers that offshoring in most cases is implemented gradually (papers B and J). It could even be hard to distinguish the boundaries between the decisions (paper F). On the other hand, some firms are being flexible in terms of “degree of reshoring” (papers B, C, and F), thus still producing the same products as they offshore but in smaller volumes. This strategy provides flexibility and the possibility to shift volumes between locations. In terms of governance mode, offshoring is made in all forms (from outsourcing to joint ventures and fully owned factories). However, paper C found that the preferred governance mode for offshoring was outsourcing, given that it reduces the risks and provides flexibility as well as facilitates repatriation since it is considered relatively easy to end the relationship with a supplier. Reshoring, on the other hand, is primarily made in
a captive mode, i.e. activities are insourced. Interestingly, three papers out of fourteen were specifically studying the organizational readiness for reshoring, concerning for example how to deal with the shortage of skills and competences at the domestic location. Thus, as part of the implementation process, a preparation phase has been identified. This is a new aspect compared to existing frameworks. Surprisingly, also articles with a focus far away from the preparation phase mention details that help in structuring its characteristics. Among others, some of the mentioned elements are the development of in-house training programs (paper B), improving efficiency and freeing space (paper K), and organizational readiness (papers H, L, and M). Naturally, after having found evidence of the reshoring preparation phase, we expected to find information also about the offshoring preparation. Even if this aspect was not widely discussed in the sample articles, some details were mentioned, as the transfer of knowledge, competences and technology from the home to the host country (papers B, C, and J), and the preparation of managers to face offshoring challenges (paper G). The offshoring preparation phase is an absolute novelty of our framework with respect to previous reshoring frameworks.

Outcomes
The offshoring and reshoring outcomes were included as new aspects compared to previous frameworks. The outcomes, categorized as problems or benefits, are highly interesting from a managerial perspective, as they could be used to derive the success factors of manufacturing relocation. But they are also relevant from a decision-making perspective, since the offshoring outcome in many cases act as a driver of reshoring. For example, insufficient quality at the offshore site is an offshoring outcome, but it is also a main driver of reshoring. This is true in survey studies as well as in several of the studied papers (papers C, G, I, J, K, and N). One question that has received quite a lot of attention is whether reshoring is reflecting a strategy change or if it is a correction of a previous offshoring mistake, i.e. if reshoring is a reaction to an offshoring failure (Fratocchi et al., 2016). From the studied papers it is evident that reshoring could be both. For example, paper G concluded that the reshoring decisions could not be completely explained by changes in relative costs between locations. Instead, they say that offshoring was made without completely evaluating risks and performance challenges, and that reshoring thus was a correction of a prior offshoring mistake. Similarly, paper C found that reshoring was implemented after continuous problems with quality at the host country site. On the other hand, in some studies the firms had explicitly stated that offshoring was not a failure (papers A and J). Paper J argue that the offshore duration (over ten years) in combination with the strategy change driving the reshoring decision, indicate that offshoring was not a failure. Interestingly, the outcomes of reshoring were not discussed widely in the studied articles. However, reshoring success or failure could possibly influence the location strategy of a firm, thus influencing the trajectory of its global operations.

Contingency factors
Concerning the contingency factors, from the analyzed articles it was clear that many contingencies play a role in influencing the offshoring and reshoring processes. However, contrarily to what was expected from the initial framework, we found that contingencies were spread all over our final framework, given that every part of the framework can become contingent to the others. A clear example is represented by the debate on the relationship between offshoring and reshoring, many studies claims that reshoring is strongly influenced by the previous offshoring decision, so much that it is worthwhile to study them together (Joubioux and Vanpouck, 2016). Therefore, the offshoring decision can be considered a contingency factor influencing how the reshoring decision is
managed. As an example, paper J argue that a captive offshoring mode makes firms less inclined to repatriate operations. The spreading of contingencies across the framework reveals the challenge to control for all the contingencies that might affect reshoring.

Conclusions
In this study a comprehensive framework was developed, with the purpose to lead future research in the field of reshoring. This represents a first effort in making research more comparable, thus overcoming the “contingencies control” challenge. Moreover, the research clearly demonstrates that even if articles are grounded on different characterizations of the ontological and epistemological artifacts, it is possible to conduct a successful meta-synthesis. This provides a clear contribution for researchers in the field of reshoring. The implications for managers are connected to the possibility to gain a wider picture over the offshoring and reshoring processes, and to have useful insights about the dynamic nature of such processes as well as of the variety of challenges that previous cases faced in multiple contexts. This study thus provides an important contribution for companies that are relocating manufacturing. The paper does not come without limitations. First, the meta-synthesis method relies on secondary data. Second, the choice to limit the considered papers to peer reviewed sources allowed to control the quality of the studies, but at the same time it might have caused the exclusion of some interesting papers. Future researches, besides trying to overcome the hereby presented limitations, could focus on the application and testing of the proposed framework in real cases, as well as on quantitative data collection.

Abstract  
In the past decades, IT outsourcing grew steadily and eventually shifted outside the boundaries of the client’s base location to low-cost economies (Han and Mithas, 2013). These events led to the commencement of offshore IT outsourcing, popularly known as ‘IT offshoring’ (Edwards and Sridhar, 2005). Our research study is exploring academic literature and research models concerning outsourcing from international literature coupled with its validity in the IT offshoring context. As the study progressed, it became evident that although there are frameworks existing for outsourcing practices in various disciplines, only a few studies have been undertaken which are related to the critical factors and its effective management in IT offshoring context (Moe et al., 2014; Kern and Willcocks, 2000; Khan et al., 2012). This research gap indicated that there was substantial scope to contribute in the sphere of the dynamics of IT offshoring within the areas of relationship intensity management.

Keywords: IT offshoring, trust, relationship management

Introduction  
Often IT outsourcing is viewed as a valued business performance mechanism to enhance productivity, cut costs and boost competitiveness for organisations (Lacity et al., 2010). The origin of IT outsourcing is linked with the externalisation of functions of facility and operations management support services in the early 1960s, as revealed by Lee et al. (2004). However, the momentum started in 1989 with Kodak’s strategy to outsource its IT (Kern and Willcocks, 2000). Consequently, the number of outsourcing engagements increased, and outsourcing was considered as a vital business strategy for managing IT (Loh and Venkatraman, 1992). Here onwards IT outsourcing grew steadily (McCarthy, 2004) and eventually shifted outside the boundaries of the client’s base location to low-cost economies. These events led to the commencement of offshore IT outsourcing, popularly known as ‘IT offshoring’ (Edwards and Sridhar, 2005).

Originally, low-cost back office services were the primary reason for
offshoring, but gradually during the late 1980s, firms outsourced substantial IT activities offshore (Oza et al., 2006). Besides software application development and maintenance activities, the magnitude of diversified IT services offshoring has steadily grown over the last decade and continue to grow further (Krishna et al. 2004). Accordingly, McCarthy (2004) claimed this trend is expected to accelerate as offshore IT services offerings are extending with significant value addition coupled with the establishment of offshore delivery facilities of large client companies globally. These centers have been created in countries such as India, China, Brazil and Russia. The developing countries evolving to undertake IT offshoring activities support such tremendous growth in offshoring.

Offshoring attained an extraordinary momentum following 2001 and continues to accelerate due to economic recession (Khan et al., 2011). Offshore suppliers increasingly upgraded their capabilities and service quality with the diverse experience of implementing complex IT projects and this way rose up the value chain. In recent years there has been the application of state-of-the-art technology, world-class infrastructure and high-quality technical manpower to cater to clients’ requirements (Khan et al., 2012). India and China are the major players in the recent years in executing a substantial number of outsourced contracts offshore. Some major offshore IT service providers in India are TCS (Tata Consultancy Services), HCL Technologies, Infosys and Wipro (Chou and Chou, 2011).

With such extraordinary progression in the volume of IT offshoring services, the proportion of failure is also escalating (Foote, 2004; Moe et al., 2014) which is becoming a major anxiety for the client firms engaged in offshoring. Therefore it elicits a need to explore this area of IT offshoring with the objective of building a framework that can contribute towards achieving a potentially improved success rate.

This study is exploring current organization theories and research models concerning outsourcing from international literature coupled with its validity in the IT offshoring context. As the study progressed, it became evident that although there are frameworks existing for outsourcing practices in various disciplines, only a few studies have been undertaken which are related to the critical factors and its effective management in IT offshoring context (Moe et al., 2012; Kern and Willcocks, 2000; Khan et al., 2014; Lacity, 2002). This research gap indicated that there was substantial scope to contribute in the sphere of the dynamics of IT offshoring within the areas of relationship intensity management and thereby this topic of study was selected.

Prior studies on the offshoring client-supplier relationship has been primarily literature reviews, case studies and opinion polls. Dibbern et al. (2004) state that although several prior studies highlight on the importance of relationship management, there is a definite lack of positivist research approach examining this aspect. Also, there are very limited research evidences on the relationship management domain viewed through the lens of social exchange theory, in the general outsourcing literature. Picking up on this gap, we intend to suggest identifying and analysing such factors that may potentially result in favourable outcomes enabling overall engagement success.

Although IT offshoring is an established business practice, the success of such engagements cannot be always predicted. Increasingly complicated nature of activities/tasks being offshored, together with the diverse execution models of offshoring engagements, may require a fresh approach to examine the client-supplier relationship implications on the overall outsourcing success. There have been an
attempt to understand some of these challenges in the operations management of IT offshoring engagements in the literature (Niazi et al., 2013; Lonsdale and Cox, 2000; Kern and Willcocks, 2000) and these studies clearly recognised the need for more focussed research in the relationship management attributes of IT offshoring. Our research study therefore is an attempt to initiate a baseline platform by which the relationship management development factors can be appreciated and recognised by the clients in order to make informed decisions relating to the identified critical factors enabling success.

The first research objective of this study is to suggest measures that can potentially increase the success rate in IT offshoring engagements by studying the interplay between the critical factors influencing the relationship intensity level of the exchange partners and. Secondly this study will identify the relevant critical factors and explore its causes and effects on the relationship intensity significance level.

**Research background and purpose**

IT outsourcing grew steadily and eventually shifted outside the boundaries of the client’s base location to low-cost economies (Han and Mithas, 2013). These events led to the commencement of offshore IT outsourcing, popularly known as ‘IT offshoring’ (Edwards and Sridhar, 2005).

This study is exploring academic literature and research models concerning outsourcing from international literature coupled with its validity in the IT offshoring context. As the study progressed, it became evident that although there are frameworks existing for outsourcing practices in various disciplines, only a few studies have been undertaken which are related to the critical factors and its effective management in IT offshoring context (Moe et al., 2014; Kern and Willcocks, 2000; Khan et al., 2012). This research gap indicated that there was substantial scope to contribute in the sphere of the dynamics of IT offshoring within the areas of relationship intensity management.

Prior studies on the offshoring client-supplier relationship has been primarily literature reviews, case studies and opinion polls. Dibbern et al. (2004) state that although several prior studies highlight on the importance of relationship management, there is a definite lack of positivist research approach examining this aspect. Also, there are very limited research evidences on the relationship management domain viewed through the lens of social exchange theory, in the general outsourcing literature. Picking up on this gap, we intend to suggest identifying and analysing IT offshoring factors that may potentially result in favourable outcomes enabling overall engagement success.

Research objective of this study is to suggest measures that can potentially increase the success rate in IT offshoring engagements by studying the interplay between the critical factors influencing the relationship intensity level of the exchange partners.

**Research methodology**

This study is mainly based on in-depth literature review, several European case studies and interviews of companies who are engaged in offshoring their work to non-European countries. A collective observation of IT offshoring from literature and interviews from IT offshoring user company officials helped identifying the
critical factors behind IT offshoring and highlighted specific challenges in their engagement success with IT offshoring operations.

The positivist perspective of research was followed in this study. Sekaran’s (2000) suggested certain steps of the research process which were adopted. These include, a systematic literature review, analysis, and the unbiased role of the researcher(s). The study setting is realistic, unit of analysis is the individual outsourcing client firm(s), and the time frame is cross-sectional.

All the critical factors identified are adapted from validated studies in the literature. Thereafter a preliminary assessment of these critical factors was carried out by industry practitioners of IT offshoring to further validate the context of the relationships among them (the critical factors). Clients in Europe participating in IT offshoring being the target population, the information collection was difficult. As the unit of analysis being individual client firm, it was rather tedious to get the interview response from senior management authorised to participate in such research studies. In the interviews, the senior management respondents had undertaken the role of authorised representative of firms and furnished information as a consolidated organisational experiences rather than personal attitudes and perception.

**Literature review**

By outsourcing of non-core activities, it reduces the effort required to manage peripheral tasks, except for the efforts needed to manage the supplier. This may allow management the opportunity to focus on the important business functions (Kakabadse and Kakabadse, 2000; Jennings, 2002; McIvor, 2000). Further, Kakabadse and Kakabadse (2005) exposed that there is a need for a greater focus on the core competency area in order to remain competitive in the market, based on interviews with 50 CEOs and findings from 747 survey responses. However, in a fast-changing economy the definition of non-core and core must be revisited on a continuous basis, as per McIvor (2000).

**Cost effectiveness**

There are alternative ways by which cost reductions can be achieved. It can be through an improved efficiency due to the application of sophisticated technology or processes and/or through the savings of manpower costs. Cost reduction in manpower costs is based on the presumption that a supplier can provide a specified service more cost-effectively due to its lower operating costs in the offshore location and access to economical manpower (Kakabadse and Kakabadse, 2000; McIvor, 2000). The offshore suppliers can provide more cost-effective services to their clients also due to having economies of scale and specialization in certain type of services contributing to increased productivity (Abraham and Taylor, 1996).

**Capitalise on supplier innovation and investment**

Rapid technological change in the market is encouraging firms to offshore services based on the specialization and availability of leading-edge skills with the supplier firm (Henley, 2006). Quinn and Hilmer (1994) recommends, collaboration with suppliers can provide access to high-quality artefacts and very efficient services without the required level of proficiency, investment in human capital, processes or information technology and infrastructure.

**Enhanced flexibility**

In order to stay competitive in the market the client firms leverage on latest
technology competence of the supplier firms coupled with the scalability features available in the offshore outsourcing engagements. Therefore, offshoring is proved to be a beneficial mechanism in the long run, through which the clients can draw these added benefits besides getting their work done at a lower cost (Deavers, 1997). Besides this, offshoring is a favourable practice as in-house style of operations may restrict flexibility by using a specific type of technology as per company internal norms (Quinn, 1999). Wang et al. (2008) also confirmed this by examining 120 companies’ performance after offshoring their IT functions.

*IT offshoring to leverage supplier competencies*

It is feasible to achieve increased service levels as clients can gain access to superior competencies from their suppliers, studied by Quélin and Duhamel (2003). Also, McIvor (2006) revealed that clients can take the advantage of access to highly skilled technical manpower resources in the supplier country that are not so easily available or highly expensive in the client’s country. Therefore, literature revealed four main motivation categories behind offshore outsourcing:

- Focus on core competency
- Increased cost effectiveness
- Capitalise on supplier investment and innovation
- Greater flexibility and scalability
- Leverage supplier competencies (e.g. technical and process)

Offshore outsourcing is thus considered to be a highly valuable corporate strategy whether used in a tactical or strategic way. Although offshoring is a valuable business strategy it also poses a lot of challenges needing special attention.

**Critical factors for overall success in IT offshoring**

Various outsourcing studies claim across other discipline suggest effective management of relationship is extremely critical to the success of an outsourcing engagement. There are only a few studies (Kishore et al., 2003; Lacity et al., 2010; Kern and Willcocks, 2000) emphasised on the importance of relationships within IT offshoring based on some of the most commonly visible factors like cultural dynamics, communication and contractual issues. This particular section discusses all the critical factors recorded in the literature of outsourcing studies.

A study of Kern and Willcocks (2000) state, factors like information exchange, effective communication and cultural integrity are critical to relationship management in outsourcing. Another study in supply chain (Brereton, 2004) also reflect similar factors stating that preparedness of parties to share information coupled with mutual respect for each other is critical to success in relationship. Meeting expectations was considered as a critical measure of success relationship success by Stralkowski and Billon (1988). This also relates to client satisfaction level in terms of success achievement that may reflect in the continuity of the engagement. Information sharing as a critical factor is also considered by Kishore et al. (2003) and is related to the aspect of level of co-operation between the engaged parties. Other researchers (Dibbern et al., 2004; Niazi et al., 2013) claim that the skills & commitment to the deliverables that was initially decided in the contract, cope with change, and to recognise added requirements may arise during the engagement time frame are the identified critical factors of success.
Therefore, based on structured literature review, the current study attempts to answer the question: What are the critical factors for the overall success of IT offshoring relationship?

The structured literature review revealed the following top 7 factors have the highest occurrences in the literature as the critical factors for overall success in relationship management of the engagements.

1. Legal contracts / contract management
2. Relationship specific investments
3. Information and knowledge sharing
4. Information security practices
5. Trust
6. Minimisation of uncertainty risks
7. Outsourcing success (expectations match).

Additionally, some of the other studies place the above factors to have an echoing effect on trust in relationship management (Sabherwal, 1999; Kern and Willcocks, 2000; Kishore et al., 2003). Therefore, this study identified trust as the central theme for the success or failure of any IT offshoring engagement.

**Trust**

Though the highest mention of trust was found as a critical factor based on the structured literature review, its importance is found to be predominantly abstract in most studies. Trust is the most significant critical factor in successful relationship is evident in the literature. The majority of research focus into trust has been found in various other disciplines like organization behavior, economics, supply chain management, social science and marketing. Level of trust in a relationship can be a measure of relationship intensity in an exchange relationship between the partners (Doney and Cannon, 1997; Tian et al., 2008).

This study adapts this view of relationship intensity combined with closely associated attributes of trust to explore further, linked with the aims and objectives. This closely related relationship attributes of trust (e.g. commitment, loyalty, dependency, reliability, sincerity, fairness, co-operation, collaboration and other variants of trust) to signify the relationship intensity are backed by literature evidence (Ganesan, 1994; Anderson and Weitz, 1989; Morgan and Hunt, 1994; Das and Teng 2002; Doney and Cannon, 1997; Dyer and Chu, 2011; Kennedy et al., 2001).

**Failures and challenges in IT offshoring**

Although IT offshoring has multiple benefits, it is not totally devoid of failures and challenges. Several industry reports enumerate the benefits and unprecedented growth of offshore outsourcing without revealing much on the rate of failures. Moe et al. (2014) debated that most papers only report the positive aspects of offshoring. There are only a few research evidences found in the area of challenges and failures in offshoring (Khan et al. 2012).

Foote (2004) examined 90 offshoring engagements and revealed that more than 50% of the offshoring engagements fail to achieve the desired objectives of offshoring, i.e. all the above listed basic motivation objectives. One such important factor that has always been under estimated is the importance of relationship issues and this was well articulated by Foote (2004).
In the literature several failures have been highlighted in the areas of requirement analysis, execution of contract, development and implementation of product and post execution support (Moe et al., 2014). However, the basis of some of the known failures are due to poor management of client-supplier relationship (Kishore et al., 2003).

There are crucial issues such as communication skills, culture adjustment, operational behaviour, and time zones difference which are significantly critical for offshoring. It is therefore needed to handle the cultural difference between the client and supplier respectfully. Foote (2004) identifies that managing cultural difference in offshoring may be more challenging than local outsourcing. Existing studies reveal a number of difficulties faced while offshoring such as increased costs of coordination (Aubert et al., 1998), distant geographical location (Herbslab and Moitra, 2001), threats associated with information security (Blackley and Leach, 1996), lack of direct communication (Pyysiainen, 2003), absence of real-time information regarding all outsourced activities (Gonzalez, 2006) and problems due to infrastructure (Barthélemy, 2001). These are illustrated as below.

Offshoring relationships are dynamic and evolve over time due to rapid changes in the global business environment and the client’s internal requirements (Kishore et al., 2004). Additionally, continuous technology improvements allow not only more volume of work but also other different types of work that are related. Changes evolving in the new business models in IT offshoring seem to require closer and more complex relationship management approaches between client and supplier to make it a success for both parties (Niazi et al., 2013).

**Initial analysis and findings**

IT offshoring is always faced with new challenges and may develop substantial risks for the clients if they are not managed properly. There are significant legal challenges to IT offshoring, which makes the achievement of strong contracts difficult and enforcing the same even more challenging. As all the activities and operations cannot be closely monitored from a distance; development of trust to complement the legal contract demands more attention to combat these challenges (Kanawattanachai and Yoo, 2002). This makes effective information security and information sharing practices as a prerequisite for success (Khalfan, 2004; Costa, 2000).

Relationship-specific investments are beneficial in developing client’s trust, cultivating supplier motivation through flexible contracts that aid in building trust as most contracts are incomplete, according to Bakos and Brynjolfsson (1993a).

As suggested by Poppo and Zenger (2002), the relational governance as a framework for control, and monitoring combined with trust-based relationship building enables reducing uncertainty risks.

Achieving greater alignment between scope, task, rewards, objectives and goals directing to the success of the engagement for both involved parties (clients and suppliers). These can be accomplished through the concept of partnership model proposed by Das and Teng (2004), considering the fact that offshoring motivations within each organisation may differ significantly.

There has been an attempt to understand some of these challenges in the operations management of IT offshoring engagements in the literature (Niazi et al., 2013; Lonsdale and Cox, 2000) and these studies clearly recognised the need for more focused research in the relationship management attributes of IT offshoring.
Our research study therefore is an attempt to initiate a baseline platform by which the relationship management development factors can be appreciated and recognised by the clients in order to make informed decisions relating to the identified critical factors enabling success.

Our initial analysis supported main motivation categories behind offshore outsourcing, namely Focus on core competency; Increased cost effectiveness; capitalise on supplier investment and innovation; Greater flexibility and scalability. Also, it added a greater emphasis for leveraging supplier competencies (e.g. technical and process). The common challenges in IT Offshoring includes outsourcing core competencies, supplier selection, poor or tight contract, personnel issues, losing control over the supplier, uncertainty risks management, long-term or exit strategies and hidden costs (Das and Teng, 2002).

Focusing on a trust-based relationship, encourages both parties, specifically the supplier to accomplish contracted tasks to exhibit enhanced performance thereby promoting performance beyond the contract (Lee and Choi, 2011).

Conclusion
This study identifies key factors via systematic literature review that are necessary for establishing a strong platform in IT offshoring relationship development. Understanding these factors may assist IT offshoring companies in addressing issues relating to establishing a strong relational intensity. Consequently, it also aids to ensure the successful outcome of IT offshoring engagements with long-lasting relationship between the clients and suppliers (Ali-Babar et al., 2007; Sabherwal, 1999).

Typical issues in client-supplier relationships are well documented in the literature (Palvia, 1995; Tian et al., 2008; Parkhe, 1998b; Krishna et al., 2004). These problems are a major cause of complex challenges being faced in the engagement that at times make the clients re-think on the IT offshoring strategy itself and some clients reverted back to the classical model of in-house or insourcing services, as reported in the literature (Foote, 2004). In case of failures, the investments (tangible and intangible) made by both parties are completely sunk. Further, it may call for additional investments to revert to the old system of in-sourcing.

The supplier side of relationship management understanding is limited to timely payments and long-standing contracts (Oza et al., 2006). The other aspect is governed by the fact that if an engagement fails, clients are at more loss than the suppliers. However, results of the study is not expected to be mutually exclusive and may be applicable to both client firms (in Europe) as well as their supplier firms, in the sense that identified critical factors will be applicable to both partners equally to realise success through strengthening their relationship.

This study is particularly relevant to the client-supplier firms already engaged in a relationship but can also be useful to those who are planning to begin their journey in IT offshoring in the near future, as a preparatory and planning platform.

Abstract

Though many have written about the concept of domestic outsourcing and offshore outsourcing, rather few conceptualisations have been elaborated for captive offshoring. Reaching beyond classic approaches, such as core competencies and knowledge transfer, we enclose captive offshoring in a framework derived from (theoretical) evolutionary biology. The resulting framework, conjoined with a literature review, brings new aspects to the decision making on captive offshoring. A research agenda is presented based on the framework and its implications. The undertaken literature review proves that this research area is a Greenfield approach and there are several questions that have not yet found an answer.

Keywords:
Captive offshoring, (theoretical) evolutionary biology, mutations, decision making
Foundations for Decision Models on Captive Offshoring from an (Theoretical) Evolutionary Perspective

1.1 Scope and Outline of Paper

Based on this evolutionary conceptualisation that captive offshoring is a mutation of the company subject to evolutionary forces, derived from (Dekkers, 2005, p. 46), this paper provides a comprehensive review of decision-making models for manufacturing companies with regard to captive offshoring by evaluating the relevant literature.

This approach complements other attempts to capture decision making for offshoring. For example, Schmeisser (2013, p. 392 ff) presents a framework that is rooted in literature rather than derived from a theoretical framework. However, those that have used conceptualisations based on theoretical frameworks have limited themselves to theories that could be contested. A case in point is the work by Jahns et al. (2006) based on: transaction cost economics, the resource-based view, and the market-based view (the last related to comments by Priem and Butler (2001) with regard to the resource-based view); transaction cost economics and the resource-based view have been found inadequate for long-term effects by Dekkers (2011, p. 959) for outsourcing. From this perspective, Wiener et al. (2010, p. 481) call for strengthening the theoretical basis for research into offshoring. Thus, we intend to extend the theoretical basis for outsourcing by including a framework derived from (theoretical) evolutionary biology; this framework should also capture long-term effects better.

After classifying and delimitating captive offshoring from other related concepts in the second section, we introduce an evolutionary framework for captive offshoring in the third section. The fourth section summarises the methodology of this particular systematic literature review, and the fifth section presents the results of this review. We present our conclusions together with a research agenda based on the developed framework in the final section.
1. Positioning and Defining ‘Captive Offshoring’

Before embarking on the development of this framework and linking it to the literature, it is necessary to delineate captive offshoring from other related concepts. For this purpose, the paper of Jahn et al. (2006, p. 222), provides an illustration, from which results that the term ‘buy’ includes also onshore (as well as nearshore and offshore) outsourcing – a concept representation we will rely on -when we use ‘buy’ as synonymous to ‘outsource’. Note that the decision to outsource or make-or-buy implies that external to the company capabilities are available to a firm that could substitute for internal processes. Thus, the interchangeability of these activities implies that even if a company has the capability to perform specific processes, it scans the (international) market in order to find some other organisation, that can also deliver this product or service, as good as itself, if not better, faster or cheaper – and opts for it. There is also an ‘in-between’ option, called ‘hybrid’ by some (Jahns et al., 2006, p. 221); we choose the term ‘shared ownership’ to stress that in which form whatsoever the companies agree to (legally) act together in order to achieve their common goal, e.g. joint venture, consortium or business partnership, the end-product is commonly owned, even if not necessarily in equal parts. This means that in distinguishing captive offshoring from other related conceptualisations, a dimension of ownership and a dimension of geographical distance should be taken into account.

[INSERT FIGURE 1 ABOUT HERE]

Thus, the classification we provide for our purpose, see 1, has two dimensions: ownership and geographical proximity, similar to Jahns et al. (2006, p. 222). This is based on the following descriptions of the dimensions:

- **Make**: in-house production, whether in the domestic country or a foreign (neighbouring) country, either before or after the decision about outsourcing or offshoring.

- **Buy**: any form of production resulting from a transaction between the company and a third party organisation, whether in the domestic country or a foreign (neighbouring) country.
• **Shared ownership:** a separate legal entity is created either under the domination of one party (dominant parent) or under equal shares (shared management). Youngdahl et al. (2008, p. 4) describe it as ‘build, operate and transfer’. Though cross-border and international shared ownerships, e.g. joint ventures, are used as synonyms, we propose this term in order to acknowledge the different vertical dimensions. We will not go into further detail about its concepts in this paper because of the focus on captive offshoring, but have included it for a holistic overview.

• **Domestic country:** the country of residence of the company, from where it conducts its economic and legal transactions.

• **Neighbouring country:** a country that has at least one common, direct border between itself and the domestic country.

• **Foreign country:** a country, that has no common, direct borders with the domestic country, because there is at least one independent territory between them.

Similar to our representation in 1 is the one provided by Jahns et al. (2006, p. 222) with the difference of chosen terminology of ‘wholly – owned’ versus ‘contractual/ legal’. We do not make the distinction between onsite and offsite (same country), as we do not consider it to be a distinct territorial dimension relevant for positioning captive offshoring.

From here on, 1 will guide the classification of terms and the evaluation of papers found during the systematic literature review.

2. **Evolutionary framework**

3.1.**Evolutionary Analogy**

For the purpose of considering mutations of organisations as analogous to organisms, and we consider captive offshoring from this perspective, Dekkers (2008, pp. 51-55) has found the following similarities between organisms and organisations; these similarities will be reflected on for captive offshoring:
- **Selection acts on mutations.** Such a process exists for organisations where the selection process finds itself in competition for customers, the acquisition of resources, e.g. suppliers, and the changes in the ecosystem of which a company is part. Thus, captive offshoring as a mutation is a restructuring of resources and processes, including control, managerial processes and interactions between actors in a company (note that captive offshoring does not change the boundary of a company in contrast to outsourcing).

- **Organisations and organisms are structurally closed.** In the case of captive offshoring, organisations remain structurally closed because the ownership of resources does not change, the boundary of the company with the environment remains principally intact.

- **Organisations, like organisms, have the possibility of self-cognition and learning.** Although the boundary at company level does not shift, the changes in resources and interrelationships may induce differences in self-cognition and learning in the case of captive offshoring at the level of manufacturing departments.

- **Developmental pathways seem to exist for both organisations and organisms.** Though there is a difference between them, Figure 2 exemplifies such a developmental model, where genetic and non-genetic mutations lead to form and function trajectories, according to developmental pathways coded in the structure of the organisation. This raises the question whether there are developmental pathways for captive offshoring.

- **The mutations are selected by the environment based on adaptive walks and the criteria of sustained fitness and evolvability.** (Dekkers, 2005, p. 150). Thus, companies that have opted for captive offshoring should be subject to adaptive walks and selection criteria.

The major difference between organisms and organisations in evolutionary terms is the presence of foresight; whereas organisms principally propagate through random mutation – ignoring group selection –, organisations have the capability of foresight. Therefore, mutations are teleological, though subject to selection and environmental changes. This also means that captive offshoring should be a result of foresight. However, there are also other evolutionary mechanisms, such as mimicking, that could lead to
the mutation of captive offshoring. Thus, captive offshoring could be a result of foresight or other evolutionary mechanisms.

From here on, we will view offshoring as a (teleological) mutation that is subject to developmental pathways for increasing fitness and to evolutionary forces caused by population dynamics and ecological changes. Thus, captive offshoring could be a result of either foresight or other evolutionary mechanisms, such as mimicking.

**[INSERT FIGURE 2 ABOUT HERE]**

3. **Analysis of Retrieved Papers**

5.1 **Decision Making on Captive Offshoring from an Evolutionary Perspective**

The detailed analysis showed that of the 50 papers, only 16 are written around the terms ‘captive offshoring’ and ‘decision making’. Hence, we are particularly interested in finding those which applied a game theoretical approach in finding an optimal solution for the decision problem of captive offshoring. We further constrained the results subject to the condition that the study also mention, or even better apply, any concept related to game theory. Only four out of 16 papers complied with this requirement: (Eischen & Singh, 2005; Gonnet, Ikeya, & Starkov, 2011; Mugurusi & Bals, 2017; Srivastava, 2008).

Mugurusi and Bals (2017, p. 64) pursue the impact of offshoring based on a case study into the purchasing and supply organisation in a global engineering company. However, it does not refer to the approach we were aiming to find. The next paper we obtained from this search is Gonnet et al. (2011, p. 1). Whereas its bibliography refers to game theories, it does not apply any of its concepts to the decision-making process. Similarly, the doctoral study of Srivastava (2008, p. 147) does not address any of the decision-making models for captive offshoring we were looking for, but rather focuses on ‘offshore sourcing (or offshoring)’ within the IT sector. The last paper, Eischen and Singh (2005, p. 1) brings into play a new discussion, which might also be related to ‘captive offshoring’, but it analyses universities, not companies, and their related workforce development in a highly competitive and technological leading environment. Although three relevant papers and one doctoral thesis out of 16 mention game theories in some way, none does more than mention the concepts.
However, there are three papers that use game theories for offshoring. One such paper, which resulted from the search of the MPEC approach to offshoring in general, is Igami (2013, p. 1). It models the effects of offshoring for investigating industry dynamics and its results suggest the incentive to offshore increases as more rivals offshore due to competitive pressure (ibid., p.1). One possibility is to apply this model to captive offshoring to see if it holds, and, if so, does it deliver the same results? The doctoral dissertation of Arisoy (2007, p. 5) into determining the most advantageous offshoring location and distribution strategies, also provides an empirical study into captive offshoring. Not incorporating any evolutionary theory, the study (ibid., p. 5) mentions stochastic methods as one way of providing a “Pareto optimal solution set for a multi-objective problem”, which can also include evolutionary algorithms. The disadvantages mentioned, including that this approach ‘does not guarantee optimal solutions and their performance depend on many factors, such as the initial population and adjustment parameters’ (ibid., p. 5), may be one of the reasons the methodology focuses on other approaches in the pursuit of the research question. Mirani (2013, p. 663) has a new perspective compared with the other studies discussed so far in our literature review. He ‘applies a morphogenetic change framework to the case study of a financial information services provider’s relationships with offshore IT application vendors over a six-year period, in order to discover the underlying causal mechanisms’ (ibid., p. 663). Mirani (2013, p. 663) characterises each change ‘by a morphogenetic cycle of three phases – structural and cultural conditioning, socio-cultural interactions, and structural and cultural elaboration’. Thus, three papers that describe offshoring refer to concepts related to game theory, but this does not yet prove their models extend to captive offshoring.

5.2 Evolutionary Biology and Game Theory

A search for ‘evolutionary biology’ and ‘game theory’ provided an overwhelming number of over 12,100 results on Scholar Google alone, but when restricted to MPECs it was limited to only 4 references. We were particularly interested in publications that combine the game theoretical approach, used to solve the dynamic environment of evolutionary biology, that is applied in an economic or macroeconomic context.
Since we already elucidated on Igami’s (2013) paper in the previous section, we will focus this analysis on the remaining three. Kroshl (2015, p. 41) mentions in his doctoral thesis that ‘Another approach to finding solutions to Stackelberg games is founded in evolutionary biology’, without investigating this avenue further; but concludes by providing an MPEC computational approach for a case of ‘… interactions between [...] companies in the electricity and emission allowance market … (ibid., p. 54)’. A similar approach is also provided in a paper he co-authored: Kroshl et al. (2015). Sen and Shanno’s (2008) research into new algorithms for computing Nash equilibria of stochastic games combines a dynamical system with nonlinear programming to find stable equilibria. This approach is motivated by evolutionary biology reasoning – providing additional motivation for using MPECs in this regard. The authors make a valid point from an evolutionary point of view, when applying game theoretical approaches in order to solve the system, namely that ‘replicator dynamics have the undesirable property that 0 is always a fixed point. This might be reasonable in evolutionary biology (an extinct species cannot rise from the dead), where the idea of course originates, but is problematic in games with individual agents. A player might very well start taking a particular action that he was avoiding before. A further source of dissatisfaction with all dynamics proposed thus far is that convergence to a Nash equilibrium cannot be guaranteed, and is often quite rare’ (ibid., p. 984). Given the fact that ‘even a two-player stochastic game gives rise to a nonlinear problem, which in general will be nonconvex’ (ibid. p. 986) leads, once again, to the formulation of an MPEC, for which they provide a solution in their research. Their approach could offer a possibility for formulating an MPEC approach for captive offshoring. Mordukhovich and Outrata’s (2007a, b) research concerns a class of hierarchical games called equilibrium problems with equilibrium constraints (EPECs). They equate equilibrium problems with complementarity constraints (EPCCs) as a type of generalised Nash equilibrium problem, which includes several complementarity constraints. The beauty of the EPECs is that their constraints are themselves MPECs and thus create a comprehensive, recursive system; see Figure 5. These papers might not be directly related to an evolutionary approach, but do provide necessary optimality conditions and propose a numerical method to solve the class of EPCCs.
4. Concluding Remarks and Further Research

The lack of literature from this perspective gives us a Greenfield approach. We offer a new insight into captive offshoring, relying on the analogy between captive offshoring and evolutionary biology, aiming to provide an innovative foundation for decision making models. This perspective is reliant on three theoretical foundations: the wholly owned externalization of production and R&D, i.e. captive offshoring, evolutionary theory and artificial intelligence. The aim of this research is to offer an overview of the current body of knowledge at the intersection of these three theoretical approaches, to introduce a new and innovative approach.

One main limitation to this method is that originates in an analogy-based approach and there might be several characteristics from the analogized theories, that might not find a corresponding interpretation when placed in the new setting. Nevertheless, if taken two by two, namely economics and evolutionary biology, economics and game theory, evolutionary biology and game theory, we found underlying literature pointing the way to this approach (see section 3). Taking advantage of the transitivity of a logical connection, in theory at least, our analogy and its underlying mathematical approach, is just as valid as the existing connections made so far in the literature.

Managerial Implications

Though, it is not a practical in its current state, this particular paper is the first step into the theoretical foundation of our vision. Based on the main characteristics of a genetic mutation, namely fitness and adaptability, and adding foresight to the equation, we look into the future possibility of proving a tool, that can predict economic failure or success for captive offshoring by evaluating if the externalization of a specific process is an advantageous step or not. Our further research will focus precisely on this topic and, if successful, can provide a model that is able to “complete” the picture for this specific decision-making process.

Abstract

Teamwork, although important in all Operations Management sectors, plays a highly relevant role in healthcare, where the main services are provided by teams. Leveraging the novelty and potential of wearable sensors, this research investigates the relationships between team coordination and surgery performance, exploring how team dynamics and communication may influence the likelihood of adverse events during routine surgery. Breast surgeries of an Italian hospital were monitored using Sociometric badges for collecting objective and systematic measures of team behaviors. Results show the importance of team coordination dynamics and team cohesion for improving surgical performance and patient safety.

Keywords: Behavioral Operations, Wearable sensors, Healthcare Management

Introduction

In the last decades, due to the increasing complexity and interdisciplinary nature of healthcare services, the use and relevance of teams has grown significantly in healthcare organizations making teamwork an essential part of effective care delivery (Valentine et al., 2015). Healthcare teams, especially in the dynamic domains (like operating rooms, emergency medicine, intensive care), commonly are assembled ad-hoc and multidisciplinary, work under quickly changing conditions, and stay together for a short period with a dynamically fluctuating team membership (Leonard et al., 2004; Manser, 2009). These peculiar characteristics, also found in aviation, military, and sport teams, make healthcare teams very difficult to study (Shah & Breazeal, 2010; Wheelock et al., 2015; Chang et al., 2017).

As shown in other business sectors, most research in healthcare claims the relevant effect of teamwork, specifically team coordination and communication, on team
performances in terms of high quality and safe patient care (Leonard et al. 2004, Manser, 2009; Burtscher and Manser, 2012; Berry et al., 2016). This position is supported by many authors in different healthcare areas: surgery (e.g. Mazzocco et al., 2009; Yule et al. 2006; Siu et al., 2016); intensive care (e.g. Dietz et al., 2014); mental health (e.g. Deacon and Cleary, 2013); neonatal resuscitation (e.g. Williams et al., 2010); and across entire hospital systems (e.g. Berry et al., 2016). Accordingly, researchers and health managers have widely investigated team behaviors in different healthcare settings to understand the possible determinants/influencing factors and to define strategies for improving teamwork and process performance (Manser, 2009).

In this context, surgery has attracted the greatest attention as a result of its preeminent repercussion on hospital budgets and its highly relevant impact on patient care and safety (Yule et al., 2006; Gupta, 2007; Jebali et al., 2006). Indeed, the operating room is one of the most complex and challenging work environments in healthcare, where teamwork failures and human errors have been shown to cause the greatest amount of unintentional harm in a hospital (Sun et al., 2018; Wheelock et al., 2015). Accordingly, past studies recognize the remarkable influence of team coordination and communication on surgical performances (Yule et al. 2006; Mazzocco et al., 2009; Wheelock et al. 2015; Siu et al., 2016).

In particular, two main aspects seem to play a leading role for the management of dynamic teams, like surgical teams: the way in which the team members coordinate themselves and the cohesion of team (Mathieu et al., 2008; Rico et al., 2008). The team coordination takes place through explicit and implicit coordination mechanisms and patterns. The balance between explicit and implicit coordination, which occur simultaneously in surgical teams, has deeply influences team performance (Malone & Crowston, 1994; Crawford & LePine, 2013). Although implicit coordination appears to increase team effectiveness, the best equilibrium between explicit and implicit coordination depends on the specific features of the tasks involved (Espinosa et al., 2004; Gorman, 2014; Butchibabu et al., 2016). For example, a higher proportion of implicit coordination compared to explicit communications leads to higher team performance for routine tasks with high interdependency, like routine surgery (Rico et al., 2008; Riethmüller et al., 2012).

On the other hand, the cohesion of team, usually enabled by the existence of Shared Mental Models (SMM) defined as common knowledge structures held by team members, facilitate the cooperation and increases the efficacy and efficiency of team coordination and communication (Cannon-Bowers et al., 1993; DeChurch & Mesmer-Magnus, 2010). Thanks to the greater sharing of objectives and ideas and to supportive behaviors, team cohesion seems to have a relevant positive effect on team performance for many different team configurations and contexts (Fisher et al., 2012; Gorman, 2014).

In spite of increasing interest and a significant amount of rhetoric around teamwork in healthcare, relatively few quantitative researches have evaluated the relationship between team coordination and surgical performance (Schmutz and Manser, 2013; Siu et al., 2016). In particular, evidences of a direct link between team coordination dynamics and surgical outcomes are scarce and not conclusive (Sun et al., 2018; Mazzocco et al., 2009). The creation of a valid and reliable measurement system is one of the main obstacles for studying team behaviors in such a context, but also elsewhere. In fact, the two most adopted approaches, self-report (e.g. interviews and questionnaires) and direct observation (or mediated through video recordings), are costly and of low reliability since they are affected by subjectivity, memory effect,
influence of the observer, and high time need for data collection (Barley, 1990; Leonard-Barton, 1990; Kim et al., 2012; Chaffin et al., 2017).

The recent advent and availability of wearable sensors and similar technologies, also referred to as sensor-based measurement tools, is offering the opportunity of measuring and evaluating teamwork through data-driven methodologies. Providing automatic and objective measurements of team behaviors, these tools can efficiently collect a big amount of data in real time, avoiding the main bias linked to typical approaches to teamwork studies and increasing the data richness, quality, and reliability (Rosen et al. 2014; Chaffin et al., 2017). Thanks to direct and quantitative measurements of individual and team behaviors, the adoption of such technology may effectively help scholars to evaluate team coordination and its relationship with the healthcare outcomes, for instance in term of care effectiveness and safety. In so doing, this approach allows to overcome or, at least, to mitigate the main limits of common approaches to the study of teamwork in healthcare and elsewhere (Chaffin et al., 2017; Rosen et al., 2014; Kim et al., 2012).

Leveraging the novelty and potential of wearable sensors, this work aims to investigate the relationships between team coordination behaviors of surgery teams and the related performance during surgical activities. In particular, this paper explores how the team behaviors and communication may influence the performance of routine surgery. A preliminary case study within the Breast Unit of an Italian university hospital was carried out to understand the effect of team coordination and team cohesion on surgical outcome.

This research also contributes from a methodological perspective, by showing the suitability of wearable sensor approaches (Chaffin et al., 2017) for studying links between team behaviors and process performance. Thus, the paper proposes this novel approach as a valid method for discovering or confirming/denying relationships between team coordination and team performance in healthcare and other fields.

### Hypothesis development

Past research showed that several errors and adverse events during surgery are caused by failures in team coordination and communication or, more generally, by non-technical aspects, rather than a lack of technical expertise (Yule et al. 2006; Schmutz and Manser, 2013; Siu et al., 2016; Gjeraa et al., 2017; Sun et al., 2018). Thus, team coordination and effective communication play a preeminent role for providing high quality and safe patient care in surgery (Bogdanovic et al., 2015; Manser, 2009; Singer et al., 2016). Accordingly, a growing number of empirical studies shows that the most severe disruptions during surgery are related to communication and coordination problems.

According to the contingency theory and past evidences of coordination studies, the communication and coordination strategy, though always very relevant, should be adapted to the specific type of surgery (e.g. Donaldson, 2001; Crawford & LePine, 2013). Indeed, the appropriate balance between explicit and implicit coordination strategies depends on the characteristics of the task involved such as the level of task uncertainty and task interdependence.

Specifically, surgical features are highly dependent on the specific surgery context, thus surgical teams should adapt their behaviors based on the peculiar surgery characteristics (Bogdanovic et al., 2015). The main aspect that characterizes surgeries is the degree of routine (uncertainty) of surgical procedures, which allows researchers to classify surgical treatments as routine and non-routine ones and to distinguish accordingly between different coordination best practices (Manser, 2009; Bogdanovic et
Regarding task interdependence, its level tends to be quite high in all surgical procedures though it can slightly change based on the specific surgical context.

Research seems to confirm that for routine surgeries, similarly to all routine tasks, a lower level of explicit communications brings higher team performance while a high level of implicit coordination has a positive effect on performances (Manser, 2009; Wheelock et al., 2015; Butchibabu et al., 2016). The explanation may be that a larger proportion of implicit coordination for surgeries with high level of standardization permits a greater focus on surgical task, thanks to the increased individuals’ free mental resources and more effective and efficient communication (Manser, 2009; Gorman, 2014). On the other hand, the exclusive use of implicit coordination has a negative effect on surgical performance when the level of task routineness is low, because explicit coordination may better synchronize team members in high uncertainty environment (Rico et al., 2008; Manser, 2009; Riethmüller et al., 2012).

First studies in this field suggested that surgical teams during routine interventions should stay focused on the tasks, limiting the discussions and avoiding unnecessary conversations (Wheelock et al., 2015; Singer et al., 2016; Keller et al., 2016). Indeed, many discussions/talks in routine surgeries are associated with poorer surgical performance and increased risks for patient safety (Tschan et al., 2015; Wheelock et al., 2015; Singer et al., 2016). Past evidences show the importance of remaining vigilant throughout a case and maintaining a high functioning team operating in a silent environment, especially when the surgical procedure presents a high level of routineness (Wheelock et al., 2015; Keller et al., 2016; Tschan et al., 2015).

On the contrary, the amount of explicit coordination behaviors and verbal communication should increase when the surgical procedures are non-standard and the level of task uncertainty is high (Sun et al., 2018; Tschan et al., 2015). Operating teams, where tasks are uncertain/not well defined at the beginning and affected by frequent change of patient conditions and needs, require more unique acts and thus need explicit coordination to synchronize team members (Bogdanovic et al., 2015; Riethmüller et al., 2012). This does not mean that implicit coordination is irrelevant, but the importance of explicit coordination and unambiguous communication rises.

Our preliminary case study involved breast surgeries, specifically quadrantectomy and mastectomy. These surgeries are done on a high level of task routineness and low uncertainty (e.g. McLaughlin, 2013), with the procedure being well defined before the start of the operation. We thus postulate a negative effect of too much explicit coordination, which implies increased communication overhead and reduced focus on surgical task. The results are affected by the specific context (routine surgery) where the procedures to be followed are well defined before the start of the operation.

Thus, considering past studies and the context under analysis, we hypothesize:

**H1: The lower explicit coordination of the surgical team by verbal interaction, the higher is the performance of the team**

The dynamics and the effectiveness of team coordination and communication in surgeries depend also on team cohesion, recognizing, in particular, the important role of Shared Team Mental Models and of a collaborative environment for providing high quality and safe patient care (Cannon-Bowers et al., 1993; Catchpole et al., 2008; Manser, 2009; Mazzocco et al., 2009; McComb and Simpson, 2014; Siu et al., 2016). Indeed, team cohesion permits team members to anticipate and support each other, to enhance implicit coordination and harmonize team behaviors, and to communicate more efficiently (Gjeraa et al., 2017; Burtscher and Manser, 2012; Gorman, 2014; Sacks et
This in its turn indirectly improves surgical performances in term of quality and safety.

In addition, a trusting and inclusive team climate seems to decrease conflicts and discussions during surgery, enhances the ability to cope with surgical problems, and increases the performance of each team members by reducing their level of stress (Dahl et al., 2017; Singer et al., 2016; Wheelock et al., 2015).

The positive effects of team cohesion on team dynamics, e.g. favoring implicit coordination, and on final surgical outcome have been shown in many different surgery contexts, regardless of the routine nature of the activities involved (Manser, 2009; Rico et al., 2008; Sacks et al., 2015). For example, Gjeraa and colleagues (2017) found that team cohesion and shared mental models may increase the patient safety during video-assisted thoracoscopic surgery. Catchpole and colleagues (2008) showed that also in more routine surgeries, like low risk orthopedic operations, team building and understanding of others’ needs decreases the occurrence of surgical problems. Nevertheless, the positive effect of team cohesion appears to be greater in contexts that need a high level of implicit coordination and for highly interdependent tasks (Rico et al., 2008; Manser, 2009; Gorman, 2014; Bogdanovic et al., 2015).

Consistent with past evidence on team cohesion we hypothesize thus:

H2: The higher the level of team cohesion, the higher is the performance of surgical teams

Method and Case study
For an effective evaluation of such relationships, a novel systematic measurement approach powered by the Sociometric Badges is adopted to obtain quantitative and reliable measures of team behaviors during surgeries. Indeed, one of the most important challenges in studying teamwork in highly dynamic domains of healthcare, like operating rooms, intensive care, and emergency medicine, is related to the measurements of team dynamics (data collection phase) that are commonly assessed by interviews, direct observations, questionnaires, and reports (Manser, 2009). Thus, they often suffer from subjectivity and memory effects, or face problems through the influence of the observer on the system (Barley, 1990; Leonard-Barton, 1990; Kim et al., 2012; Chaffin et al., 2017).

Sociometric Badges are wearable sensors invented at the MIT Media Lab, for catching the “honest signals” inherently related to human behaviors and group interactions (Pentland, 2008; Olguín et al., 2009b). Indeed, they can automatically and directly measure individual and collective dynamics in a quantitative way, exploiting four different sensors: accelerometer, microphones, Bluetooth, and IRDA (Olguín et al., 2009). Thanks to its sensors and the increased stability, sociometric badges offer a systematic way to quantitatively investigate the individual and collective patterns of behavior overcoming the limitations previously cited.

Moreover, sociometric badges are able to guaranty the privacy as it is impossible to determine the content of the conversation or identify the speaker from the sociometric data. This way, these badges prevent obstacle related to privacy laws (very important in the healthcare field) and are likely to be far less intrusive than human observers, potentially limiting any social distortions to the data (Olguín et al., 2009; Rosen et al. 2014). The suitability and usefulness of Sociometric Badges for monitoring behavioral variables is proven by past research (Kim et al., 2012), also in the healthcare field (e.g. Olguín et al., 2009b; Bucuvalas et al., 2014).
Given the lack of research systematically evaluating the behaviors of surgery teams and the novelty of the measurement approach, an exploratory case study (Yin, 2017) was carried out for this preliminary investigation.

Case study
We collected data from 66 breast surgeries in the Breast Unit of an Italian University Hospital. All cases are about cancer related problems and were chosen randomly. The surgical team composition is the following: two surgeons, one scrub nurse and one assistant nurse. Frequently there are also one or two additional surgeons or nurses. In general, the analyzed team were composed by a minimum of 4 to a maximum of 7 people.

To study the surgical team dynamics and their influence on performance, we collected the individual and collective behaviors of surgical team members for each surgery using the Sociometric Badges. Each team member wore the Sociometric Badge for the entire duration of the surgery. Sensors allowed collection of team interaction data thought the accelerometer, microphones, and Bluetooth data. Due to the position of the Sociometric Badges under the surgical scrub for safety reasons, IRDA data was not collected. In the end, we collected and analyzed the behavioral data of 292 individuals for about 380 hours of recording.

In addition to the sociometric data, we also gathered the main features of the surgeries (as for example the duration) and we requested team members to fill out a survey about the “team cohesion” for each different team they take part. Finally, the surgical performance was evaluated though the occurrence of surgical glitches (the binary variable Glitches ON/OFF was reported for each surgery), given that providing a safe and effective operation is the main goal of surgery and that a surgical glitch may have a highly relevant repercussion on patient health and on hospital expenditure.

Findings
To assess the proposed hypotheses, Pearson’s correlations and logistic regression were performed using the data collected during the 66 breast surgeries. The behavioral variables, recorded using the Sociometric Badges, and the “team cohesion” were taken as independent variables, while the Glitches ON/OFF, useful for evaluating the surgical performance, was employed as dependent variable. In addition, three main features of the surgeries, i.e. the surgery duration, the number of people inside the operating room, and the size of the monitored operating team, were used as control variables.

“Pearson’s correlation” was useful for getting a first insight of the data and supporting the next phases of regression analysis. The significant correlations obtained were quite numerous and, for reason of brevity, are not reported here. However, it is noteworthy to point out that there are no significant correlations between the control variables and the dependent variable.

To measure the potential effect of independent variables on the dependent variable, we use logistic regression because the dependent variable, Glitches (ON/OFF), is binary (Hosmer and Lemeshow, 2004). A logistic regression model using three independent variables (Silence, Team Cohesion, and Mirroring) was build. This model is strongly significant, with all the variables included statistically significant, and explained a significant portion of the variance as reported by the Nagelkerke $R^2$ obtained (Nagelkerke, 1991).

The logistic model discloses the positive effect of Silence, i.e. the percentage of time in which the team member and all others in their proximity were silent, on performance. Indeed, a higher value of Silence implies a lower likelihood of experiencing a surgical
glitch. The model also showed that *Team Cohesion* has a positive effect on performance, diminishing the chance of glitches during surgeries. *Mirroring*, included as third variable of the model, appears to have a positive effect on surgical performance, by decreasing the surgical glitches. Considering *Mirroring* as a proxy for assessing the level of implicit coordination during surgeries, the regression model suggests that implicit coordination behaviors positively affect team performance.

The model achieved supports hypothesis H1, by confirming that a high level of explicit coordination (high level of verbal interaction) negatively affects the outcome of routine surgeries while implicit coordination (high level of mirroring) appears to favor it. If team members have to coordinate continuously through explicit verbal interactions they tend to lose focus on specific tasks and the probability of glitches increases. This result is aligned with the insights gained from informal interviews we had with practitioners and direct observations carried out to explain the findings obtained.

The model also supports hypothesis H2, showing the positive influence of the cohesion of teams on the surgical outcome through decreased likelihood of glitches. Team cohesion increases the supportive behaviors by team members, the team communication efficacy, and the practitioners’ engagement, and thus positively affects surgical performance.

In order to confirm the validity of findings, regressive models using the control variables were tested. The first check was to add the control variables, individually and together, to the logistic regression model obtained. In any case, model performance did not considerably improve and the inserted control variables were non-significant. The second test was to build the model simply using control variables. Also in this case, no model built with the control variables was significant. These tests appear as a strong confirmation for the validity of our findings, ruling out any potential effect of the control variables.

**Conclusions**

This paper investigates the relationships between the team coordination behaviors of surgery teams and related surgical performance, using wearable sensors for the analysis. The use of direct and quantitative measures for evaluating team behaviors helped to overcome the main limits of popular approaches for measuring team behaviors and teamwork, and permitted us to find more reliable linkages between team coordination and process performance.

The results of this explorative case study show the impact of team coordination on performance, supporting the idea that surgical performances and adverse events during surgery are affected by team behaviors and non-technical aspects of the team as argued by past authors (e.g. Gjeraa et al., 2017; Yule et al. 2006; Siu et al., 2016). Specifically, our findings support hypotheses *H1* and *H2* highlighting that:

- The likelihood of adverse events and errors during routine surgeries is lower if the members of surgical teams coordinate implicitly rather than through explicit communication. This confirms the positive effect of implicit coordination and the negative effect of explicit communication on routine surgery performances.
- The likelihood of adverse events and errors during routine surgeries is lower if the surgical team displays a higher level of team cohesion. This confirms the relevance of team cohesion for obtaining better surgery performances.

In line with past literature on team coordination (e.g. Rico et al., 2008; Butchibabu et al., 2016; Manser, 2009), a first interpretation of findings seems to endorse that a higher
proportion of implicit coordination leads to greater performance in this context, thanks to a larger focus on tasks and more effective and efficient team communication. Moreover, team cohesion appears to have a positive influence on surgical performance because it seems to harmonize team behaviors, to increase the communication effectiveness, and to create a collaborative environment where people are inclined to back each other up (Rico et al., 2008; Fisher et al., 2012; Gorman, 2014).

From a methodological perspective, this research exploiting the Sociometric Badges also provides a contribution to the problem of “how to” quantitatively investigate behavioral aspects in dynamic environments. Findings support the effectiveness and suitability of wearable sensors for investigating team dynamics and their relationship with process performance in healthcare, overcoming the restrictions of previous approaches like memory effect, subjectivity, and the influence of the observers.

Managerial implications
This study also provides a relevant contribution from a managerial perspective. The results obtained and their interpretation allow us to provide some practical insights for healthcare managers, medical staff, and their training activities. Regarding routine surgery, we recommend to increase the proportion of implicit coordination behaviors, for example fostering deliberative communication rather than reactive communication (e.g. Butchibabu et al., 2016). Healthcare managers may plan appropriate training sessions to help medical staff. In addition, we suggest to the surgical team to set up a well-defined task distribution, and to be more focused on the job, by avoiding unnecessary conversations during surgery. For enhancing the ability to prevent and cope with surgical problems, as also supported by past evidence (e.g. Sacks et al., 2015), healthcare managers should pay attention to the formation of cohesive teams and to the creation of collaborative environments.

Limitations and suggestions for future research
This research has several limitations that point out directions for future research. The first is due to the exploratory nature of the work. Drawing on a single case study, results might be affected by the particular application/cultural context. This is a common issue for many behavioral studies that limit generalization (Tröster et al., 2014). Besides, although findings are statistically significant, the sample size is quite limited. In the near future, it may be interesting to repeat this study in a different cultural context to confirm our findings and to strengthen the practical recommendations. In addition, since different surgery contexts (routine vs innovative procedure) may require different coordination needs and interaction patterns (e.g. Manser, 2009), we suggest extending the research by reapplying this methodology to different types of surgical operations. Finally, more teamwork research enabled by wearable sensors is also desirable to further prove the effectiveness and suitability of this novel approach.

Abstract

Health care systems are under pressure to improve care performance. Patient flow has been recently gaining increased focus, supported by developments in care pathways, IT, and new management principles. There has been limited research, however, looking at these elements together. This paper serves as a preliminary review of care pathways and health IT, aiming to highlight the main aspects that can contribute to patient flow improvement. In addition to reviewing a selection of literature, a model is proposed showing the relation of the research elements. This paper will serve as input to a full systematic review at a later stage.

Keywords: Patient Flow, Care Pathways, Health information technology

Introduction

Health care systems are under pressure to improve quality of care and performance (Radnor et al., 2012, van Lent et al., 2012). Health care organizations in many countries have tried many approaches to improve care performance, though these improvement projects are often seen as either to local, specific, limited – or downright failures (Radnor et al., 2012). Recent studies in Operations and Supply Chain Management (OM/SCM) have emphasized how analyzing and improving patient flow from a larger, chain perspective can increase efficiency and maintain or improve care quality (Drupsteen et al., 2013, De Vries and Huijsman, 2011). These initiatives, however, need to align with clinical practices and tools, such as care pathways and health IT – since these phenomena are an essential part of the work life of physicians, nurses and other health personnel, and are likely here to stay for the foreseeable future.

Care pathways, also known as clinical pathways, are being used extensively in health care organizations to improve and standardize care (van Lent et al., 2012, De Bleser et al., 2006). A care pathway is a “method for the patient-care management of a well-defined group of patients during a well-defined period of time (De Bleser et al., 2006),” which also includes facilitating communication, and coordination of activities in patient care.
Care pathway research has had a mainly clinical focus, aiming at for example improved clinical guideline adherence; however, care pathways have potential in improving integration and coordination of patient care processes and services – i.e. in the planning and control of patient flow from a managerial perspective (De Vries and Huijsman, 2011).

Health care consists of a growing number of IT systems, including Electronic Health Record (EHR) systems, Computerized Physician Order Entry (CPOE) systems, etc. (Jones et al., 2014). However, these systems mainly serve clinical, administrative or financial purposes, and therefore are not used as a tool to effectively integrate and coordinate the patient flows within and between organizations. Procuring, implementing and adopting an IT system that transcends the internal and external boundaries of departments and organizations in the health sector may allow for improved coordination and integration of care processes – and thus, improved patient flow (De Vries and Huijsman, 2011, Devaraj et al., 2013). To realize this potential, however, it is necessary to explore how health IT can support care pathways (Neame et al., 2019).

This paper is a precursor to a full systematic review on care pathways and health IT, as they relate to patient flow from an OM/SCM perspective. The main aim is to (i) provide a preliminary review of the extant literature, (ii) propose a conceptual framework showing the relationship between care pathways and Health IT in supporting patient flow, and (iii) define the key dimensions to be expanded upon in the full systematic review. The full systematic review will serve as a stepping-stone to improved patient flow both by highlighting the key mechanisms of care pathways in patient flow and the necessary functionality that health IT must have to support patient flow.

The paper has the following structure. First, a short review of OM/SCM in health is gone through, where after an explanation of patient flow. Second, the research methodology is described, relating to how this paper was developed and how it will relate to the later full systematic review. Third, the selected articles are summarized – one section with care pathway literature, another section with IT support for care pathways. Fourth, the insights on care pathways and health IT are discussed in relation to patient flow improvement, where after a conceptual model is developed and key dimensions identified. Finally, the paper concludes with describing the research relevance of the coming full systematic review.

**Health care from an OM/SCM perspective**

OM/SCM research aims at improving the delivery of products/services through effective design, management, and planning and control of resources. Recently, literature and research on OM/SCM in health care has attempted to tackle various issues ranging from operational to strategic developments in managing patients, materials, resources and many others (Dobrzykowski et al., 2014). The way forward, however, still does not appear to be straightforward. Radnor et al. (2012), for example, analyzes Lean literature in the context of health care, exploring why Lean appears to be an “unfulfilled promise.” When so many authors suggest Lean could “solve” the problems of suboptimal health care performance, why do problems still subsist?

Other authors, such as De Vries and Huijsman (2011) focus on a broader SCM view, noting the relevance of SCM in improving the health care systems and mitigating the challenges that have arisen. By viewing health care organizations as a part of a supply chain, integration can be assessed and improved through a variety of phases – taking into account a holistic view of the care processes. Thereby, value-adding processes can be identified and focused on in improvement initiatives. Ultimately, however, the priority for health care is to provide high quality care to patients – and thus, patient flow improvement is of utmost importance (Drupsteen et al., 2013, Devaraj et al., 2013).
Patient flow from an OM/SCM perspective
Patient flow refers to the transferring of patients along various care steps, which can be both within and between organizations. Many studies have focused on studying patient flow within hospitals (van Lent et al., 2012, Devaraj et al., 2013), however a need for broadening the scope to include more care steps in and between various organizations has been called for (Drupsteen et al., 2013, De Vries and Huijsman, 2011). Improving patient flow requires us to understand the drivers and barriers to patient flow (Drupsteen et al., 2013, Devaraj et al., 2013). The Theory of Swift, Even Flow (TSEF) can be used to shed light on this (Drupsteen et al., 2013, Devaraj et al., 2013, Schmenner and Swink, 1998).

Schmenner and Swink (1998) proposed TSEF in an attempt to create an encompassing theory, based on OM/SCM principles, to explain productivity differences of factories – and later applied the theory to services (Schmenner, 2004). The authors initially describe a variety of “laws” that have surfaced in the OM/SCM field (Schmenner and Swink, 1998) including i) Laws of variability: the greater the variability in the process, the less productive the process will be, ii) Law of bottlenecks: the bottleneck in a process will limit the throughput of the entire process, iii) Law of scientific methods: the use scientific methods can improve productivity, iv) Law of quality: increasing quality of a process will also improve productivity, and v) Law of factory focus: focusing on a limited number of tasks will be more productive than carrying out many tasks.

TSEF which states “the more swift and even the flow of materials (or information) through a process, the more productive that process is (Schmenner and Swink, 1998).” TSEF explains why the laws described earlier hold true. TSEF ultimately rests on three concepts, namely value-added and non-value-added work, bottlenecks and variability.

Value-added and Non-value-added work: Work can be either value-added, or non-value-added, meaning that some work adds value to the process whereas other work is unnecessary and considered “waste.” As such, for example, the law of scientific methods, when applied on the value-adding processes, will in fact yield higher performance.

Bottlenecks: The bottleneck is that point in a process that has limited capacity, compared to the other process steps. The bottleneck will therefore limit the throughput of the entire process, given that the bottleneck is necessary for the process. As such, using the law of scientific methods specifically on processes that relate to the bottleneck can improve performance. The law of quality also explains how “temporary bottlenecks” may prop up if a process needs to stop due to errors or defects, therefore higher performance can be increased through improved quality.

Variability: Variability, measured by variance in time spent per process step, timing, or quantities, impacts the ability to attain even flow. Therefore, reduction in variability is desired to attain an even flow. For example, the concept of factory focus is logical in that a focused factory will naturally reduce the variability by only producing a handful of products and limiting the number of possible process steps.

As can be seen, TSEF can explain performance of certain processes through the careful examination of value-added work, bottlenecks and variability. Thus, if the concepts and tools used in health care directly address the concepts as described in TSEF, then a more swift and even patient flow may be possible. Therefore, TSEF will be used as an underlying framework exploring which elements of care pathways and health IT are conducive to improving patient flow. Care pathways and health IT will be treated as two different constructs that can be used in conjunction with each other to improve patient flow performance - represented in Figure 1. The double-sided arrow shows that care pathways and health IT may or may not influence, support or put constraints on the other.
Based on the theoretical framework, two discussion questions have been developed. These questions serve to position the literature and findings in relation to the goal of patient flow improvement. The questions are as follows:

1. Which aspects of care pathways are conducive to patient flow improvement?
2. Which health IT functionalities are conducive to improved patient flow in care pathways?

In the discussion, the various attributes identified from the literature for care pathways and health IT are then discussed in relation to TSEF, and more specifically, their impact on value-adding work, bottlenecks, and variability. See Figure 2 below. The double-sided arrow again shows the relationship is not necessarily one-directional.

![Figure 2 Structure for Discussion](image2)

**Research methodology**

As stated earlier, this paper is a preliminary review that will be used as input to a full systematic review later on. The research design for the full systematic review is a modification of the process outlined by (Tranfield et al., 2003, Kitchenham, 2004). The process consists of four main phases, including 1) Planning, 2) Preliminary search, 3) Full systematic review, and 4) Reporting and Dissemination. This paper will cover the preliminary search phase, as the aim is to identify the main aspects of relevance for patient flow improvement. This paper will therefore contribute to refinement of the key dimensions to be explored in the full systematic review.

For this preliminary review, a selection of relevant articles were taken from a structured search on Scopus, Science Direct, Emerald and Google Scholar. Search strings were used to focus on the two main domains. Combinations of “care pathways” and “literature review” and synonyms were used to select literature relating to care pathways. For the second domain, “care pathways” and “information technology” along with various synonyms were used.

The goal for the first selection of literature on care pathways was to gain an understanding of the definition, content, outcomes, and unresolved problems that care pathways have in the health care sector thus far. The goal for the second selection on care pathways and information technology was to understand which functionalities are necessary to support care pathways, and the issues that exist in relation to these functionalities and systems – including availability of current systems and/or implementation challenges.

The search was initially conducted for the period of 2008 – 2018. However, one article outside this time period was included in this preliminary review, Lenz et al. (2007), due to the high relevance. The articles were chosen if they included a) a thorough literature review, b) had at least 50 citations and c) had a main goal as previously described for the literature selection. Four articles for each research stream were chosen to ensure a manageable, yet representative, view of current research.
Overview of selected literature
This section goes through a selection of literature from care pathways and health IT research. Table 1 lists the selected literature reviews, along with notation of the journal, research method, and corresponding research area (RA) to which they pertain. These articles are summarized independently, focusing on the main message and issues of each article. The material identified in the summaries provides input in subsequent discussion section where care pathways and health IT are discussed in relation to TSEF.

Care Pathways
Care pathway research has not agreed on a single term, so articles may use care pathway, clinical pathway, care path etc. Here, the term “care pathway” is used for simplicity.

Allen et al. (2009) is a systematic review of care pathways. They aim to explore when care pathways are effective (and not), depending on their context and content. In general, care pathways were found to improve coordination, efficiency, guideline adherence, service quality, to name a few benefits. However, the authors suggest that it is not enough to know the benefits, it is also necessary to explore exactly what care pathways are and why certain elements of the care pathways lead to improvements. This can range from development, implementation, and content, to the actual use of care pathways. The authors are adamant that, for relatively predictable care pathways, improvements in service quality and efficiency can be expected. Less predictable care pathways could serve more difficulty in extracting any benefits from care pathway implementation. In general, care pathways could need further research looking at the “supporting mechanisms” for both implementation and adoption. The authors also suggest that the research has not focused on the ability for care pathways to serve as both an accounting tool, as well as a coordination tool.

Rotter et al. (2010) is a systematic review from the Cochrane database. This review focuses on evaluating the effects of care pathways on professional practice, patient outcomes, length of stay and hospital costs. The authors limit the review to articles that show a rigorous, quantitative methodology including randomized controlled trials, controlled before and after studies, and interrupted time series analysis. Care pathways are defined as being a structured multidisciplinary plan of care. In addition to this, the authors conclude that care pathways must fulfil three of the following four criteria: translate guidelines/evidence into the local context, include detailed steps of care, include timeframes, and standardize for a specific disease or condition. The findings that favor...
care pathways in improving care focus on reducing complications, improving documentation and reducing the length of stay. Costs proved difficult to evaluate with some studies reporting reduced costs whereas others reported increased costs. The study focused on hospitals, and therefore did not look at the impact of costs or other outcomes on other organizations involved in the care processes.

Schrijvers et al. (2012) is a conceptual paper, looking at care pathways from an OM perspective. The authors use the European Pathway Association (EPA) definition of care pathways, and state that care pathways should improve patient outcomes, safety, satisfaction, and optimize resource usage. The authors distinguish between “clinical” and “care” pathway – stating that clinical pathways are located solely within a single clinic. The authors also discuss “care streets,” which refer to care pathways within focused clinics for specific illnesses. The authors then review the scientific basis for care pathways, including Critical Path Method (CPM), Business Process Redesign (BPM), and others. The paper ends with advantages and disadvantages of care pathways. Advantages include reduced waiting time between processes, reduced errors, increased coherence in the care process, cost reduction, and job satisfaction increase (due to clearer responsibilities and more autonomy). The disadvantages include dehumanization of work, increased costs in data collection, reduction of job satisfaction (due to pressure to meet time constraints and reduction in variation).

Health IT support for Care Pathways
Care pathways do show potential in being supported by IT, however research has been lacking (Neame et al., 2019). The following literature highlights studies that attempt to distinguish the main elements for supporting care pathways.

Lenz et al. (2007) discusses guidelines, care pathways, and IT applications that can support these. Guidelines are evidence-based and used to inform physicians, and care pathways are used to implement guidelines. Therefore, based on the equipment a hospital has, guidelines may be adapted. In addition, care pathways often designate which resources are needed, including staff and equipment, and time horizons for processes in the pathway. IT applications, as the authors explain, can support care pathways – though are not necessarily required. To improve care, IT applications need to become an integral and routine part of work. The authors develop and test an IT application for a care pathway. Lessons learned included 1) make the application clear, simple, and not overloaded, 2) clearly separate “recommendations” from actual decisions that are carried out, and 3) do not automatically select “default values” in the workflow. The authors also stressed that suitable training and knowledge were essential – for example, if the pathway suggests a treatment that was not normally done, the staff might document in the system that the treatment was done but not actually carry it out. Documentation and the care process are therefore closely related since documentation of the steps are only “promises” if documented prior to administering them. Thus, feedback is critical to ensure the care process is actually carried out.

Wakamiya and Yamauchi (2009) focus mainly on the necessary functions of Electronic Medical Records (EMR) to support care pathways. The need for integrating care pathways with electronic systems, such as EMR, is argued both due to inevitability of a technological transition, and due to opportunities technology holds in improving care pathways. The authors propose six standard functions for “electronic” care pathways, including 1) displaying: displaying the care pathway in relation to the electronic medical
records, 2) recording: records should be computerized, such that all events are recorded, 3) ordering: it should be possible to order and cancel orders for medications, rehabilitation, etc., 4) editing: It should be possible to edit care pathways at the organizational level, 5) variance: variance from care pathways should be recorded, and 6) statistics: statistics should be possible to be extracted from the systems. The authors explore the availability of these standard functions in several IT vendors. Most of the suggested functions are available; however, no single vendor provided a “complete product.” Therefore, the authors urge that the functions listed be used in future software development of vendors of “electronic” care pathway solutions.

Gooch and Roudsari (2011) focus care pathways and information systems, but also reconcile this with the concept of “workflows.” Clinical workflows refer to tasks related to the care process and the allocation of the tasks to the various providers involved. The authors explain differences between clinical guidelines, clinical protocols, and care pathways. These range from high level, generic to specific and variance-based. EHR systems are seen as a possible support tool, where care pathways can be “computerized.” Ultimately, the authors aim to explore and develop guidelines to implementation of a process-oriented health information system where care pathways are a foundation for the workflow. They review the challenges of implementing process-oriented systems, and various approaches to facilitate implementation – ranging from EHR integration, clinical workflow integration, and general systems implementations. The authors conclude by stating the implementation issues are a major challenge, and that pathway and system implementation research needs to be richer and focus on both processes and outcomes.

Discussion, model development and key dimensions
In this section, two broad questions are addressed regarding which aspects of care pathways and health IT are conducive to patient flow improvement. A conceptual model is developed, and thereafter the key dimensions for further study are highlighted.

Which aspects of care pathways are conducive to patient flow improvement?
As can be seen in the literature, care pathways are multifaceted and may lend themselves to facilitating a swift and even patient flow within hospitals and between health organizations.

Care pathways have a unique role in the identification of value-added and non-value-added care processes. On one hand, care pathways actively implement evidence-based practices, which, in theory, should improve patient outcomes (Rotter et al., 2010). However, in some cases, the patients may not necessarily need to go through each and every care step, as stated in a standardized care pathway. This brings out the question of whether certain care steps should actually be undertaken, even though they may not necessarily be value-added, or whether each care pathway should be individually adjusted based on the patient’s specific context.

In addition to the value-added care processes, care pathways inherently are applied in a specific organizational context (Allen et al., 2009), with various supporting processes such as capacity planning, purchasing, inventory management etc. These supporting processes, although not contributing directly to the patient care, are necessary given the fragmentation of healthcare (Drupsteen et al., 2013). As such, developing organizational processes to support care pathways, and the related planning and control, is a crucial yet underdeveloped research area. Care pathways in themselves are based on CPM and other such principles (Schrijvers et al., 2012), yet the organizational context needs to be addressed to a further extent (Allen et al., 2009).
The standardization of care processes for specific illness or conditions, as found in care pathways, serve to reduce variability. This can limit the variety of decisions made in coordination of the patient care, when different people in different departments or organizations carry out the various process steps. Care pathways may even serve to guide the development of a focused factory or specialized clinic to handle specific illnesses (Schrijvers et al., 2012). This can reduce the variability substantially, and thus improve the flow of patients. Much of the literature on care pathways also addresses the concept of coordination, and that applying care pathways will improve coordination by easing the transition from one stage to the next in the care process (Allen et al., 2009).

Care pathways can plainly state which resources are necessary for the entire care process for specific illnesses or conditions, based on evidence-based medicine (Allen et al., 2009, Rotter et al., 2010). For the local context, this allows for the analysis and improvement of bottlenecks in the care process. Bottlenecks will necessarily have a negative impact on the ability of care providers to perform steps within necessary timeframes. The literature reviewed did not necessarily consider bottlenecks as a necessary impediment to patient outcomes, though a reduction of throughput time (as measured in length of stay) was a desirable outcome of implementing care pathways (Rotter et al., 2010). Research on planning and control of such critical resources often addresses care pathways only in passing (Hans et al., 2012, De Vries and Huijsman, 2011). The link between planning and control and care pathways is of relevance, however, given the increase in care pathway usage (Rotter et al., 2010, van Lent et al., 2012).

In conclusion, care pathways have many elements that can help support a swift, even flow of patients. They serve to identify value-added and non-value-added processes for the care, as well as supporting organizational processes. Care pathways can reduce variability of patient care by allowing for a standardized offering, based on the latest clinical evidence, in which health personnel are involved and up-to-date on exactly which processes should be carried out. They also, in identifying the various processes, can be then followed up based on indicators, such as throughput time, to manage the bottlenecks that are present in the care pathway.

Which health IT functionalities are conducive to improved patient flow in care pathways?
The literature on health IT is mainly positive to the ability of IT to support care pathways, however the necessary functionalities and quantitative impact of IT remain elusive. Some aspects will be discussed now, which could facilitate a more swift and even patient flow.

Based on the value-added and non-value-added processes identified by the care pathways, Health IT can be used to create a standardized workflow for certain illnesses, therefore reducing variability that clinical staff face when treating patients (Gooch and Roudsari, 2011). Value-added and non-value-added steps can also be individually evaluated more effectively through the help of clinical decision support.

Health IT can reduce variability by making the next steps in the process of care explicit and easily accessible. This can be done through the use of checklists which give a routine and systematic follow up of the care processes (Wakamiya and Yamauchi, 2009, Lenz et al., 2007). Given that the checklists and routines are in a system does not, however, ensure that health personnel do in fact carry out the various tasks. This means that the health IT must lend itself to being a part of the everyday tasks of health personnel and give feedback if one of the tasks has not been carried out.

Health IT can allow for access to capacity availability, as well as historical information on performance of care pathways. This can highlight the bottlenecks that exist within each particular care pathway. In this way, IT could support the better
planning and managing of resources in each of the care pathways for each individual patient – given for example if some tasks can be done in a different order, in parallel, or with a different resource.

As a conclusion, the literature on IT support for care pathways is quite limited, with a focus on improving the workflow at an operational level – that is, for use by doctors, nurses and other health personnel. Nonetheless, applying IT in support of care pathways for inter-department and inter-organization coordination, planning, and quality management – as to address improved value, reduced variability, and effective bottleneck management – may provide a more swift, even flow of patients in hospitals and other health organizations (Devaraj et al., 2013, Drupsteen et al., 2013)

Key Dimensions and Conceptual Model development

Based on the discussion of the research questions regarding care pathways and health IT, the following key dimensions are used to understand the relationship between care pathways, health IT, and patient flow:

- Care pathways attributes:
  - Care process steps identification
  - Time horizon of care process
  - Resource identifications

- Health IT attributes:
  - Documentation of care process
  - Workflow and checklist functionalities
  - Planning and decision support functionalities

- Organizational context of care pathway and IT
- Evidence-based medicine

These key dimensions are supported by the use of care pathways and health IT, and serve to support the three foundations of swift, even flow as described by Schmenner and Swink (1998). Therefore, a conceptual model has been developed which has included care pathways, health IT, the key dimensions identified. The result is shown in Figure 3.

![Figure 3 Conceptual Model relating Care Pathways and IT to Patient Flow](image)

The conceptual model illustrates how the organizational context and evidence-based medicine directly impact the care pathway and IT required to provide care. Care pathways, with the identification of standard time horizons, resources, and process steps may serve to support value-added care, bottleneck management, and variability reduction. Health IT may provide support for documentation and information sharing for the care pathway, facilitate good routines through workflows and checklists for health personnel, and enable decision support both for clinical and organizational planning processes.

Conclusion

This preliminary review, and the planned systematic review, will be the first to the author’s knowledge to consider care pathways and health IT in relation to patient flow
from an OM/SCM perspective. Shedding light on the ability of care pathways and IT to improve patient flow can be of great value, especially in terms of the developments in technology, such as the increasing adoption of mobile devices, cloud-based services, and ubiquitous sensors, which can integrate clinical, logistical, and financial information.

In addition, more research on specific functionalities and design of IT based on the elements of TSEF should be carried out. The impact of home-based follow-up technologies should also be considered in the context of TSEF.

Abstract
The relevance of the integrative component in supply chain management (SCM) has been linked to the positive impact of integration on performance. Hospitals, which are under pressure to improve performance because of increasing costs, are a unique context to explore integration since the supply chain (SC) is multi-functional. By combining a semi-structured literature study and an in-depth single case study, this paper analyses the managerial practices that are contingent upon the integration in the SC of medical consumables in hospitals, and proposes interventions that can secure performance.

Keywords: supply chain integration, managerial practice, hospital materials management

Introduction
The relevance of the integrative component in supply chain management (SCM) has been linked to the positive impact of integration on performance (Frohlich and Westbrook, 2001). However, doubts about the applicability of integration have been addressed, particularly related to the context, arguing that performance depends on the contingency under which integration is applied (Van der Vaart and van Donk, 2008), i.e. the position of the supply chain (SC) partners, the level of uncertainty or type of suppliers. An empirical study of supply integration in the Mexican apparel industry concludes that tight coupling does occur and are vital to SC success, but also that tightness at one point in the network might require looseness elsewhere depending on the context of the SC (Arroyo et al., 2018). Contingency and managerial practices, i.e. how integration is realised, is crucial. There are concerns about integration, however, since it is not very well defined, difficult to measure empirically, and different aspects of integration might be important under different contexts.

With increased costs and restricted budgets (Volland et al., 2017, Chen et al., 2013), the pressure to improve performance and deliver high quality health services, more efficiently is evident. The SC of hospitals, containing multiple integrative aspects (a broad set of clinical care services and materials, covering multiple specialist functions and managerial levels, involving patients), is an interesting and unique context to explore integration, managerial practices and the relation to performance. Drupsteen et al. (2013) suggests that hospitals, with their many specialties, functions and sharing of resources
could pose different barriers and enablers to integration. Hospitals are expected to provide high availability of quality services and materials critical for patient care under circumstances with varying and unpredictable care pathways (Moons et al., 2019). Thus, there is a strong case for integration mechanisms between functions and managerial levels (strategic, tactical and operational) in order to fulfil the objectives of hospital SCs.

In literature, there is limited understanding of the integrative aspects in hospitals (Drupsteen et al., 2013, De Vries and Huijsman, 2011), particularly the managerial practices of the integration context (Volland et al., 2017, De Vries and Huijsman, 2011). Compared to patient treatment, material management has not been given high priority in hospital management research, except from the few studies mainly focusing on operative material flow issues (Moons et al., 2019). This study aims to explore this, by analysing the managerial practices that are contingent upon the specific integration requirements of the medical consumables SC, and to propose interventions that can secure adequate performance. As De Vries and Huijsman (2011) put forward, SCM in health care should especially address integration in terms of the multi-dimensionality of the operations.

The remainder of this paper begins with elaborating on the literature before a discussion of the research methodology. Thereafter, a hospital case is used to analyse the integrative context and managerial practice. The paper concludes by discussing the findings in relation to the previous literature while proposing recommendations for improving performance in hospitals and future research.

**Theoretical background**

This section explores the literature about integrative managerial practises in hospitals and proposes an analytical framework.

The supply chain literature, in general, defines integration according to *constructs* such as interaction, collaboration, and cooperation (Flynn et al., 2010, Pagell, 2004, Frohlich and Westbrook, 2001) which characterise integration as a removal or dampening of functional barriers appearing within and between organisational units. van Donk and van der Vaart (2004) propose five integrative aspects that can be used to understand the practices performed within interfaces in the SC, namely; organisation, physical flow, information flow, product development and planning and control. We adopt these five aspects when exploring the hospital SC literature, and add integrative performance attributes. Each aspect is analysed below, first with a reference to the general integration literature and second to the literature on hospital operations.

The integrative *organisational* aspect concerns the relationship and the type of partnership with buyers, suppliers and internal company units (van Donk and van der Vaart, 2004). Drupsteen et al. (2013) distinguish between the *span* of integration (which and how many units are integrated), the *scope* of integration (which aspects of the organisation are integrated), and the *intensity* of integration (the level of integration). For hospitals the span of integration include external SC operations which are supplier related processes, as well as the internal operations of functions (Moons et al., 2019). The scope of the integration can be the flow of patients, or the materials flow (Volland et al., 2017, De Vries and Huijsman, 2011). For the intensity of integrations, the literature seems to focus on the relationship, such as different types of collaborative models, and does not address the management practices to a large extent.

The integrative *physical flow* aspect relates to the connections of the material flow (Frohlich and Westbrook, 2001) in the SC. The hospital literature has particularly explored collaborative concepts such as vendor managed inventory (VMI) (Haszlinna Mustaffa and Potter, 2009), stockless replenishment method (Rivard-Royer et al., 2002), two-bin Kanban system (Moons et al., 2019), and “ward box” (Bhakoo et al., 2012) in
order to find better ways to increase performance. Common between these concepts is the need to manage resources and control cost by reducing stock levels (De Vries and Huijsman, 2011). However, the literature suggests that in spite of the performance potential of these concepts, integration might be hindered due to a lack of information and information sharing (Moons et al., 2019, Volland et al., 2017).

The integrative flow of information aspect relates to the connectivity of information and information- and communication technology (ICT), e.g. what information is shared and use of technologies such as electronic data interchange (EDI), scanners and material requirement planning (MRP)-systems. In hospital SCs, limited access to information about stock levels, lack of universal product number classification systems, low forecasting accuracy, and limited information sharing across the SC often hinder tighter integration (Volland et al., 2017, Chen et al., 2013). Adoption of management information systems, data standards and data capturing technologies (barcoding, radio frequency identification device (RFID)) has been slow in hospitals (Rossetti et al., 2012); these require personnel time for scanning, human accuracy and include high costs of adoption and implementation (Moons et al., 2019).

The integrative aspect of product development is the mutual involvement in developing new products and process improvement. The volume and variety of physical goods carried by hospitals is high and increasing. Categories of consumables, custom procedure trays and sterile items constitute the majority of the products applied (Moons et al., 2019). For process improvement, the hospital SC literature is rich, particularly regarding hospital supplier collaboration and how to improve processes by performing planning and operations together (Mandal, 2017). For the product development dimension, however, this integrative aspect in literature is scarce.

The integrative planning and control aspects relates to the directing of activities, making the situation predictable and dampening uncertainty (Childerhouse et al., 2002). The manufacturing literature argues for the need to design the planning processes according to the environment (Kaipia and Holmström, 2007, Jonsson and Mattsson, 2003). If the planning environment is characterised by high uncertainty, as in hospitals, due to being unique, complex and dynamic causing uncertainty (Moons et al., 2019, Bhakoo et al., 2012, De Vries and Huijsman, 2011), a high level of integration is recommended, and vice versa. Relevant planning variables are product, operations, demand and supply (Ivert et al., 2015). For hospitals, the demand related variables include high variability, uncertainty and unpredictability of demand (Moons et al., 2019). Demand is driven by the patients diagnosis and physicians preferences which are based on their medical training, experience with specific brands and context specific demands. There is a disconnect between those who make the buying decisions, those who actually do the buying and those who pay for the consumables which might affect demand. The product related variables include the material cost which varies between high value special equipment used in operating rooms, and thousands of different types of less expensive consumables used for patient care (Bhakoo et al., 2012). The operational related variables are logistics, inventory/storage, procurement and ordering. Multiple storage rooms exists within the hospitals (Moons et al., 2019), often with limited stock tracking possibilities. The logistics responsibility is often fragmented among several units causing coordination and integration problems. Logistics related activities are often performed by medical staff, taking away time from patient care. The supply related variables include a fragmented supplier base (Moons et al., 2019).

Performance indicators that can improve processes at hospitals can be categorised as quality, time, cost and productivity metrics (Moons et al., 2019). In this study these metrics are applied when analysing the present performance of the SC of medical
consumables. The categories of performance indicators are operationalised as *lead time*, *stock levels*, *turnover rate* and *warehouse capacity*. The metrics serve as an input for decision making and to identify inefficiencies.

To summarise the literature the following analytical framework is proposed and applied to analyse the case study (Table 1):

We shall also briefly reflect on the findings from the analysis from a system theory perspective, in particular De Leeuw’s (1976) control paradigm (it should be noted that “control” in this context refers rather to the overall goal of managerial practices, than to control as described in the integrative planning and control aspects). Four basic aspects are required to be able to effectively control a certain system, i.e. keep its performance within an acceptable range (1) the availability of a goal (2) a sufficiently rich set of steering actions (3) a model of the controlled system and (4) information about the state of the system. We are interested in gaining a better understanding of how integration, or the lack of it, is related to achieving effective control.

**Research methodology**

This section describes the research methodology of the study.

A literature study was conducted, drawing on the current body of knowledge about integration in hospitals SCs. The literature was explored by adopting a semi-structured approach based on keywords and snowball technique, searching in Google scholar, Science Direct and Scopus. An analytical framework was developed from literature and guided the case study.

The integrative aspects are analysed by an in-depth single case study of a Norwegian hospital. The case study was the preferred strategy (Yin, 2009) since the aim was to explore the managerial practices that are contingent upon the integration features of the hospital. A call for in-depth case study research has been made, emphasizing the complexity in the various medical SC (Mandal, 2017). Medical consumables, as one of the main medical SCs, are a significant component of hospitals budgets and highly interrelated to patient care. The selection of the case is motivated by the characteristics of the hospital; consisting of the many specialist functions, patient categories, centralized
sourcing and logistics units containing a supplier base, and warehouse system. The hospital is also one of the largest hospitals in Norway in terms of employees and patients. The unit of analysis is the medical consumables flow through the suppliers, warehouse, and specialist units at the hospital. The method gave access to rich and in-depth data.

Findings are based on data from interviews of key personnel, observations at the hospital and warehouse, and analysis of quantitative SC data from the ERP system. Data are analysed according to the analytical framework proposed in Table 1.

Case analysis
In this section, the case study is analysed according to the framework presented above.

The SC of consumables consists of the care units at the hospital, and a logistics unit (inventory/distribution) located outside the hospital. The inventory contains a central warehouse that receives, stores and/or cross-docks all consumables from external suppliers to the hospital’s many stocking points at the care units. Thus, the external interface of the supply chain is between the suppliers and the hospital, and the internal interface is between the logistics unit and the hospital’s care units. The following Tables (Table 2 to 4) summarize the analysis of the case data.

<table>
<thead>
<tr>
<th>Table 2 Integrative organisational aspect</th>
</tr>
</thead>
<tbody>
<tr>
<td>Organisation</td>
</tr>
<tr>
<td>--------------</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

| Span | The stocks at the care units are mostly replenished by (personnel) the central warehouse based on VMI principles. However, when required care personnel may also order. The central warehouse manages the central inventory and stocks at hospitals, ordering from suppliers and distribution/logistics. A central procurement unit at the hospital is responsible for sourcing and supplier/contract management. |
| Intensity | For replenishing stocks at the hospital, a VMI model is applied. Supplier relationships are regulated by yearly contracts following public procurement clauses. Functional organisation of internal supply chain domains. |

Table 2 indicates that the interfaces in the SC are managed in different ways. The VMI model applied between the logistics unit and the care units at the hospital indicates a high level of integration between the internal functions, while the relationship between the hospital and its suppliers seems to be less intensive.

<table>
<thead>
<tr>
<th>Table 3 Integrative physical and information flow aspects</th>
</tr>
</thead>
<tbody>
<tr>
<td>Physical flow</td>
</tr>
<tr>
<td>Information flow</td>
</tr>
</tbody>
</table>

At the hospital, the push principle is the mechanism driving the majority of the physical flows, and ordering and replenishing decisions are based on demand expectations and experiences, adjusted by variability in demand and lead time (Table 3). For these items, the only information available about stock levels and replenishment requirements is acquired through manual inspections. Approximately 20% of the stock at the hospital is...
controlled by MRP-principles, while the central inventory is fully controlled by MRP-principles.

The case study did not reveal any data indicating product or process development between the units in the supply chain.

Table 4 Integrative planning and control aspects

<table>
<thead>
<tr>
<th>Planning and control</th>
<th>Demand variability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Product range complexity</td>
<td>High variability in orders from hospital and order deliveries from suppliers per day. See figure 12 and 13. Table 4.</td>
</tr>
<tr>
<td>Operational; level of fragmentation</td>
<td>Total number of items 2,826. The pareto-analysis show that out of the total number of items, 50% of the demand stems from 132 items, while 20% of demand contains 2,304 items. See figure 8.</td>
</tr>
<tr>
<td>Supplier base complexity</td>
<td>Numerous stocking points at the hospital. Multiple layers of stock locations and buffers. Orders placed by care and logistics personnel. Care and specialist decides which item is ordered (based on preferences).</td>
</tr>
<tr>
<td>Supplier base complexity</td>
<td>In total, there are 180 suppliers. The pareto-analysis show that 50% of the supply to the warehouse comes from 8 suppliers, while 20% of the supply comes from 128 suppliers. See figure 10.</td>
</tr>
</tbody>
</table>

Table 4 characterises the SC planning and control environment as complex, consisting of demand and supply variability shown by the variability per day in the number of order lines to and from the warehouse (Figure 1 on the next page).

The Pareto-analysis shows that a low number of suppliers are responsible for supplying a high share of the items, and that a low number of items represent a high share of the assortment (Figure 2). These figures indicate a planning environment consisting of supply and demand variability, and a limited number of items and suppliers that dominate, while a high share of items and suppliers are not highly active. Additionally, considering the fragmented (multiple types of stock) stock structure at the hospital, where care and specialist preferences decide which or type of item to be ordered, the inventory system can be considered complex and multi-layered.

Metrics indicating the performance of the SC of medical consumables are illustrated in Figure 3 and Figure 4. The average lead-time from suppliers and the standard deviation of the lead-time are shown in Figure 3. The average lead time is approximately one week, while the standard deviation is up to three days. We also see that for the standard deviation there is a long tail, which indicates a high uncertainty for some few products. Further, a detailed analysis shows that for the top-20 suppliers, the lead time is short and varies between 3-8 days, but the standard deviation is much higher than for other suppliers.

Figure 4 illustrates the level of cycle stock (the number of consumption days covered by the stock level), which indicates the level of over- or understocking. From the figure, it can be seen that the coverage for many of the products are high, and clearly above the level needed in order to compensate for demand and lead time variability. Figure 4 shows the inventory turnover rate at the warehouse. A high turnover rate indicates a good fit between the demand and stock level, and vice versa. The analysis shows that for a high number of products the turnover rate is low, and for several products the turnover rate is less than 5 times/year and not more than 10 times/year.
Discussion
This section discusses the managerial practices of the integration of the SC of medical consumables, and proposes interventions that can ensure adequate performance.

Hospitals operations has a long tradition for specialised and functional organisation of work/responsibility by applying management practices based on knowledge from clinical
disciplines. In hospitals, the primary activity is centred around patient treatment and care provision, resulting in specialised units and competence centres organised in a logical sequence of treatments supported by resources such as physicians and nurses, medical devices, operating theatres and consumables (De Vries and Huijsman, 2011). This creates value and organising activities according to a value chain logic where the aim is to perform a fixed set of activities (typical for manufacturing operations), while the actual value hospitals create is in solving patients’ problems, which requires a different value chain logic and organisation (Stabell and Fjeldstad, 1998). Recent studies indicate a need for alternative management practices in hospitals because of inefficiency caused by increased demand for hospital services, treatment complexity and budget restrictions (De Vries and Huijsman, 2011).

In the case, the organisation of the SC of medical consumables is functional, with logistics, procurement and stock at hospitals as the main internal units and suppliers as the external actors. This is a practice followed by most hospitals (Moons et al., 2019). The integration between the supplier and the hospital is managed by standard contractual terms/conditions with limited focus on logistical performance. The interface between procurement and logistics is also restricted, since the logistics unit does not provide any input about logistical criteria or performance requirements to procurement when suppliers are selected or contracts negotiated. The managerial practices are less focused on collaborative mechanisms which can lead to sub-optimal behaviour in the SC; suppliers acting upon contractual terms lacking specific criteria (such as lead time, frequency) securing an efficient flow of consumables, and logistics/replenishment decisions influences by risk of either overstocking or understocking of items. The level of safety stock, turnover rate and lead time metrics in Figure 3 and Figure 4 may indicate inefficiency caused by less integrated interfaces. Collaborative SC contracts typically contain incentives for risk sharing between the supplier and customer based on principles such as buybacks and revenue sharing (Wong et al., 2009), having a positive impact for the SC. Integrated planning models such as S&OP would secure integrated process between the involved actors, including suppliers (Ivert et al., 2015).

The basic flow principle in the SC of consumables is the “push/deliver-to-stock” principle, applying buffers of items along the SC and in each unit (multiple socks the hospital) to minimize risk and secure availability. This managerial practice and limited integration, indicates first the need of high quality and safety requirements (availability) at the hospital, but can also be an indication of a less coordinated stock system since the performance metrics shows high stock levels and low turnover rate of items (Figure 4). However, the opposite practice (high level of integration) is demonstrated by the stock replenishment model applied (VMI) between logistics and hospital units. VMI models at hospitals are found to give a positive performance impact due to the improved quality of the replenishment decisions (product and quantity) (Haszlinna Mustaffa and Potter, 2009). These management practices secure high availability, dampens the risk of understocking, and are critical for physicians in carrying out their work.

Exploring the replenishment process, reflections about the efficiency of the manual stock inspections and ordering procedures, and the lack of integration to electronic information and ICT support are evident. Not only is this practice highly labour intensive, but it can also lead to risk of over- or understocking due to incorrect decisions. Additionally, for the logistics and procurement units the functionality of the ERP-system is restricted to transactional purposes (replenishment, order tracking, inventory monitoring), and is not integrated with the analytical functionality of the system. This prohibits them from monitoring performance. This functionality is only accessible through the ICT-competence centre that makes reports based on requests from users.
The SC planning environment of consumables contains several of the complexity features indicated in literature, with demand uncertainty, supply variety and heterogenous product mix as the most distinctive characteristics (Chen et al., 2013). In order to mitigate uncertainty, the managerial practices for such environments in order to mitigate uncertainty should be able to adapt to a planning horizon covering the length of the variety cycle, to align demand and supply, and the strategic and operational planning level (Dreyer et al., 2018). The planning horizon of consumables at the hospital are short-term; weekly operations plans and weekly input from hospital units and suppliers. This might lead to sub-optimal utilization of resources, such as the warehouse capacity and the distribution system to the hospital units, particularly the workforce (using overtime in peak-periods and excess capacity in off-peak periods). Figure 1 illustrates the variability of the warehouse operations. To level the capacity, the proposal is to design an integrated planning process with a longer time horizon, covering the length of the variety cycle, integrating planning across functions, suppliers and planning levels.

To summarize the discussion and to propose integrative interventions, we apply the control paradigm of De Leeuw’s. Effective control of the entire SC is achieved by breaking it down into a set of smaller sub- and aspect systems, each controlled by its own controller focussing on a specific goal (or set of goals), e.g. a centralized purchasing organization focussing on establishing frame agreements that secure reasonable prices, adequate product quality and environmental performance, the logistical unit focussing on cost efficient storage at the warehouse and further distribution to the hospital, and the care units at the hospital focussing on securing availability of the items close where they are used by the medical personnel. In the case each controller seems to meet the four conditions for effective control in the context of its own system, and thereby, contributing to the stability of the “entire” system (Ashby, 2013). Still, the analysis also showed how the performance of one system can influence, or set the premises for another one, e.g. the purchasing system providing the “input quality” with which the logistical unit has to work. This leads to the proposal of the following integrative interventions that can secure adequate performance for the consumables SC:

- Introduce an integrated tactical planning process: across internal hospital units and levels, includes suppliers
- Apply a longer planning horizon, covering the variety cycle
- Change to collaborative supplier relationships and contracts, containing coordination mechanisms
- Collaborative and automated replenishment models supported by ICT, access to real time information about stock levels and information sharing in the SC.

Conclusion
The study is the first to analyse managerial practices of integrations of medical consumables SCs for hospitals, contributing to proposals of interventions that can ensure adequate performance. Collaboration, integrated planning and information access are proposals for managerial practices that are contingent upon the medical consumable SC. The study adds to the existing literature by identifying the need for collaborative and tactical integration between levels and across functions/organisations. Managerial contributions are the interventions proposed.

The study can be strengthened by a full systematic review. Also, by including several suppliers’ elements in the study, the managerial and integration dimensions can be enriched. To further strengthen the financial and performance impact of the managerial practices, adding a more quantitative and systematic approach to measure performance can be added.

Abstract

The study sheds a light on the SCM integration strategies in the healthcare arena. This type of projects tends typically to target the most complex items: (i) medical devices and (ii) operating room materials. Healthcare organizations look for industrial partners capable of offering high quality standards of logistical services; in fact, the key economic benefits are represented by (i) stock’s management optimization and (ii) reduction of warehouse management costs. As for enabling conditions, (i) standardization, (ii) top management commitment and (iii) strategic relevance of the logistical function are widely considered as key aspect for the successful implementation of these projects.

Keywords: healthcare, supply chain, integration, partnerships

Literature Background

The Supply Chain Management (SCM) field is widely recognized as part of the main scientific literature of Operations Management (OM) and it has been in the last years a hot topic of the top OM journals becoming a dominant theme in operations management research (P. Kouvelis et al. 2006; L. G. Sprague, 2007; N. DeHoratius, E. Rabinovich, 2011). The SCM term appeared for the first time in literature in the mid-1980s and it’s fundamental pillars are attributable to operations research assumptions of 1960’s. However, in the last 30 years, the Supply Chain literature has been growing up especially in the industrial and manufacturing sectors with a straight focus on product-based firms (M.C. Cooper et al., 1997; D.Q. Chen et al., 2013). In fact, many researchers have been studying the supply chain strategies of firms coming from different industries, like automobile, manufacturing or fashion industry (Brun and Castelli, 2008; Vanichchinchai, 2012; Qi et al. 2009).

At the origin, the SCM was seen as a simple process of planning, implementing and controlling the operations of the supply chain (P. Pounder et al. 2013), however the
concept has evolved in the years and today it is recognized in literature as “the integration of business processes from end user through original suppliers that provides products, service and information that add value for customers” (M.C. Cooper et al., 1997, pp. 2).

Around the SCM concept, both in academia and practice, there isn’t a clear vision and meaning (J. T. Mentzer et al. 2001) and, additionally, it’s commonly confused with a logistic concept; however, unlike the latter, SCM is better comparable to a more comprehensive approach that aims to coordinate the functions, the processes and the relations within the organizations and across the supply chain; whereby supply chain shall mean a “network of organizations that are involved, through upstream and downstream linkages, in the different processes and activities that produce value in the form of products and services delivered to the ultimate consumer” (Christopher 1992, p. 17)

Recently, the healthcare sector has attracted the attention of researchers in the area of Operations and Supply Chain, mainly because it is becoming increasingly complex and dynamic. SCM in healthcare is a recent concept that is getting attention due to the promotion of activities integration (procurement, logistics, production and distribution of goods). Especially in the Italian National Health System, the SC integration (or partnership) is seen as a tool to increase both productivity and quality within healthcare processes. Nevertheless, the implementation of the Supply Chain Integration (SCI) strategy in the healthcare sector is still far from common, although the use of SCM is expanding rapidly between healthcare provider (G. Bensa et al., 2010), also due to the performance improvement pressure in the healthcare services linked to the limited resources and to the need to achieve more value (F. Lega et al. 2013).

The partnership along the supply chain is a relatively new concept that has been gaining a strategic importance; indeed, Supply Chain Integration is viewed by management as a tool to increase productivity and improve quality (Lega et al. 2013). In the literature, Supply Chain Integration has been studied from different perspectives. Many researchers have focused the attention on the integration with customers or buyers; while others have analyzed the upstream integration or rather the integration with suppliers (C. Gimenez et al. 2012). The implementation of a Supply Chain strategy based on partnership is useful to overcome the traditional competitive barriers between supply chain members and create mutual benefits leading towards information flows increment, low uncertainty and a more profitable supply chain. The benefits born form this alliance allow supply chain members to gain higher financial and operational performance through reductions of costs, low inventories throughout the supply chain, and increased levels of shared information (M.J. Maloni, W.C. Benton, 1997; Z. Yu et al. 2001).

In this study, we will focus the attention on the partnership between suppliers and healthcare providers (Hospitals, Local Health Authorities, etc.). The Supply Chain Integration in the healthcare field, specifically related to the hospital-supplier partnership, was defined by Chen et al. (2013) as “the extent to which the business processes between a hospital and its key suppliers are strategically coupled and unified as a whole” (pp. 392).

As underlined in the past studies, mainly in the industrial sector, it’s possible to implement integration along supply chain in numerous ways. In fact, the buyers (in this case the healthcare provider) can choose different integration approaches that have growing up exponentially due to technological innovations (e.g. RFiD system, Electronic Data Interchange, Electronic deposit account) (A. Chircu et al. 2014). Because of technological innovations, it’s possible to reach a greater information flows and achieve real-time processing and transmission of information required for supply chain decision-making (D. Prajogo, 2009; B. Ageon et al. 2013). Other types of integration practices, such as Vendor-Managed Inventory, pro-active management of expired goods (Y. Yao et
al. 2005; D. Power, 2005), Just in Time approach (S. Qrunfleh, M. Tarafdar, 2013), consignment stock and physical management of the warehouse by the supplier (S. Villa 2012) are moreover in rapid expansion even among healthcare firms.

SCI can be supported by organizational requirements to strengthen the collaboration with suppliers; previous researches have highlighted several enabling conditions that can be summarized in eight organizational conditions needed to allow collaborative relationship, these are: i) IT endowment of logistic process to make information transparent and available at the right place, at the right time, and in the right hands; ii) process standardization; iii) strong commitment of top management; iv) strategic relevance of logistics; v) skilled employees across department and organizational functions; vi) bargaining power; vii) control system of Supply chain of performance and viii) clear goals of improvement; (D. Power, 2005; T. R. Crook et al., 2007; S. E. Fawcett et al. 2008; S. Villa, 2012). However, it’s suggested that there could be some principal conditions that allow a successful partnership with supplier (M.J. Maloni, W.C. Benton, 1997; S. Babbar et al. 2008), but isn’t still clear what are the major bridges in practice.

Many authors have underlined several benefits that lead managers to implement a successful supply chain integration; generally, when the management choose to integrate supply chain, it expects an important return from the suppliers in terms of process improvement and a positive impact on operational performance (C. D. Brennan, 1998). On the other hand, there is a substantial body of literature that has identified barriers that obstruct the successful integration with suppliers (S. E. Fawett et al. 2008). In previous literature, managers have reported many difficulties in the process implementation of SCI strategy. Nevertheless, the research regarding the effects of the variables that impede the implementation of integration is still lacking, which limits the ability to find effective solutions to the processes integration along supply chain. Thus, it is worthwhile to investigate the main barriers to supply chain integration (R. G. Richey et al. 2009).

For this reason, the present paper tries to address three different questions:
- What are the integration strategies that Healthcare Firms try to implement with their suppliers?
- What are the benefits and the barriers of different integration strategies?
- What are the organizational conditions for a successful integration strategy?

It’s also important take into account that the healthcare processes are characterized by a series of specificities that inevitably influence the range of available SCM strategies. The healthcare industry has historically viewed itself as operationally different from other businesses (J. De Vries, R. Huijsman, 2011). The Hospital Supply Chain (HSC) is fairly unique and characterized by a high complexity that doesn’t affect the industrial sector; this due to the clinical operations that need an adequate and accurate supplies of goods (e.g. drugs, medical device, etc.) to meet appropriately the different patient’s needs. Moreover, the complexity is due to the thousands of different types of healthcare goods implicated in the supply processes, which can assume diverse classification (e.g. there isn’t a universal number classification for the same product), characteristics, volumes and economic values (D.Q. Chen et al., 2013). Besides, the procurement process is influenced by physicians that step inside the decision-buying process of healthcare goods (e.g. medical devices) requesting precise product specifications and making, as a matter of fact, the buying decisions (E.W. Ford, D.P. Scanlon, 2007).
These characteristics, that distinguish the HSC from the traditional concept of supply chain, make it management more complicated and knowledge-intensive. In addition, it must be noted that in Italy – as in many other developed countries – healthcare delivery organizations are publicly owned and, therefore, the design and execution of SCM strategies need to take into account all the features and specificities that make public institutions different from the private ones.

First, the range of actions available to public managers is limited by a series of political constraints. Political dynamics result in frequent policy changes and the imposition of short time horizons on public managers mainly guided by institutional rhythms linked to political elections. Developing sound long-term SC strategies and innovation projects is therefore more difficult in this context (Zanjirani et al., 2009). Secondly, public organizations face a variety of stakeholders who place demands and constraints on their managers. The presence of different stakeholders (e.g., taxpayers and recipients of services or industrial groups) requires public organizations to pursue different and sometimes conflicting objectives. Furthermore, it has frequently been argued that public agencies have distinctive goals, such as ethics, equity or accountability, that do not exist in the private sector (Flynn, 2007). To this extent, government often use procurement as a tool to promote a variety of important, broader public policy objectives (Arrowsmith, 1995; Harland et al., 2007) such as economic goals, social goals, environmental goals. Thirdly, public organizations are often designed and structured around the principles of the bureaucratic model. Public sector organizations have more formal, less flexible and more risk-averse decision-making procedures than do their counterparts in the private sector (Farnham and Horton, 1996; Bozeman and Kingsley, 1998). For example, public contracts are often awarded subject to rules and principles that are intended to ensure equal supplier treatment, nondiscrimination, and transparency and to reduce the risk of corruption. In this sense, as outlined by Moore (1995), often in the case of publicly owned organizations the value added has nothing to do with the actual result accomplished, but it is linked on how the process itself is designed and executed. In this case the respect of laws and regulations, in the execution of the procurement process, is essential in order to accomplish relevant public goals (such as equity, accountability and legality).

Research question and methodology

In order to address these three research questions, the authors have adopted a survey research strategy (Forza, 2002), targeted to the Purchasing/Logistic Managers of Healthcare organizations (Hospitals, LHA, IRCCS, etc.) placed in North-Centre Italy. The purpose of the survey was to capture the state of the art in the healthcare sector regarding supply chain integration (SCI) strategies. After an initial section concerning general information on the respondent and on his/her organization, the second section of the questionnaire aimed at capturing the perceived benefits, barriers, and organizational conditions of SCI, through questions that required answers on a 1 (strongly disagree) to 7 (strongly agree) Likert scale. The last section of the questionnaire consisted of open questions focused on the most relevant integration project undertaken by the healthcare organization in the recent years, with the purpose of identifying and reaching a deeper understanding of the top three improvement projects experienced by the management.

As suggested in the literature on survey-based studies (Forza, 2002; Hensley, 1999), because a new scale had to be developed for this study, we relied on existing contributions in order to state our questions. Before administering the questionnaire, we tested it first with academics and then with a selected number of managers, who could follow in the target population. Such checks let us gain a positive feedback on the completeness of the
questionnaire’s items (as reliable descriptions of the main constructs addressed in our study) as well as on their ability to clearly convey such concepts to target participants to the survey.

The study has been conducted on a restricted population of healthcare organizations, in fact the initial population consisted of nearly 200 units. In this study only those placed in the Northern-Central Italian regions that met one of these two criteria were included: i) public healthcare organizations (either hospitals or Local Health Authorities - LHA) ii) private hospitals with more than 400 beds. The final target population for this analysis consisted of 135 units. With 54 collected questionnaires, the response rate was 40%. The breakdown of the sample was as follows: 9 public hospitals; 6 private hospitals; 26 LHAs. The average length of stay in the current organization was 15.3 years; the numbers of year of experience in the current position was 8.4. These numbers let us assume that respondents were experienced managers, fully aware of the phenomenon under analysis.

In order to better interpret the findings stemming from the survey, we carried out interviews with the respondents of 8 organizations that had described the most innovative/interesting integration projects (in the third section of the questionnaire).

The final step of this research consisted of a focus group with the respondents to the survey and with the Purchasing/Logistic Managers of some selected healthcare organizations, who attended our presentation and provided feedbacks on the evidence of the study.

**Empirical evidence**

The evidence from the survey shows that, among the 54 sampled organizations, 78% of them have implemented at least 1 integration project, while the average number of projects undertaken in this field is 6.4, the maximum being 30.

Available data shows that, out of a total number of 261 implementation projects reported in the survey (classified by type of integration practice adopted and area of implementation), sampled organizations try to achieve a higher level of integration with their suppliers through the adoption of just in time, which is by far the most widespread practice mentioned in this survey (41 projects reported). It is followed by collaborative forecasting (38 projects reported) and then by consignment stock (36 projects reported). Details on the integration practices adopted are reported in Table 1.

</tbody>
</table>

Focusing on the area of implementation, the most recurrent ones concern medical devices and materials used in the operating rooms (54 projects for both), followed by prostheses (39 projects). Details are provided in Table 2.
The evidence reported in Tables 1 and 2 shows a remarkable degree of maturity of the sampled organizations, since the most recurrent types of projects and areas of implementation demonstrate a preference toward challenging projects (e.g. JIT for medical devices).

Moving to the benefits achieved through supply chain integration, reliability and timeliness rank in the top positions (average values 5.7 and 5.3), while exploiting the innovation potential of the supplier and establishing long-term relationship reports the lowest means (4.5 and 3.8). Because, especially for some benefits, values were characterized by a rather remarkable degree of variability, we synthetized the evidence on the most relevant benefits by classifying all of them on the basis of their average and standard deviation. The outcomes of this classification are described in Figure 1.

An item was considered either “high” or “low” comparing its mean with the average value reported by all the others. According to this description, only items characterized by a low standard deviation and a high average are likely to be relevant in and highly regarded by most organizations, regardless of their specificities. Similarly, benefits with low standard deviation and low average are unanimously raked low by the vast majority of the respondents.

The same approach was used in order to assess the impact of supply chain integration on the economic benefits, enabling conditions and barriers. The outcomes are reported in Figures from 2 to 4.
Concerning the economic benefits, those related to stock management seem to be most widespread and appreciated (namely stock management optimization and warehouse space reduction). Moving to the enabling conditions, our survey highlights the relevance of some organizational factors, as the strategic relevance of the Logistic function as well as the commitment of the top management for the success of an
integration process. Also process standardization appears as a critical condition, in line with what is commonly suggested in extant contributions on the prerequisite of change initiatives’ success. Finally, concerning barriers to implementation, the cost of the technology and, in particular, the integration of IT systems with the suppliers seem to be critical issues to be addressed.

Correlations between the number of projects implemented by the organizations, on the one hand, and organizational and economic benefits, enabling conditions and barriers, on the other, have been computed. These indices, reported in Table 3, witness a sort of “learning effect”, in that the higher the number of projects implemented, the better the perception on the benefits that can be achieved and the lower the one concerning the barriers. However, it is worthy pointing out the positive correlation with enabling factors, which seems to show that over time respondents gain a high awareness about the conditions that must occur in order to successfully implement an integration project.

<td>-0.06</td>
</tr>
</tbody>
</table>

Finally, we controlled for the nature of the sampled organization, in order to understand whether such a feature drives the perceptions of the respondents. Indeed, we found out that average values of LHAs are lower for economic and organizational benefits and for enabling conditions, while such an average is higher for the barriers (see Table 4).

Conclusions
The study sheds a light on the SCM integration strategies in the healthcare arena. As expected, given the wide diversity of supplies that characterize this sector, the study has identified different types of practices; however, it must be noted that the majority of the projects have focused on the two most complex hospital items: (i) medical devices and (ii) operating room materials.

Despite the diversity of practices, the study has identified common trends along all the different dimensions investigated.

First of all, healthcare delivery organizations look for industrial partners capable of offering high quality standards of logistical services in terms of reliability and speed/timeliness. This is confirmed by the wide agreement about the fact that the key economic benefits, derived from these partnerships, are represented by (i) stock’s
management optimization and (ii) reduction of warehouse management costs. On the contrary, the possibility of establishing long-term relationships with the suppliers is not considered a positive spill-over of these strategies. This is mostly likely strictly related to the public nature of these institutions where, due to the political rhythms, it is difficult to define long term relationships and, furthermore, legal constrains make impossible arranging for long-term contractual agreements.

Standardization (either process and product standardization) in not considered a positive consequence of this integration strategies but, on the contrary, an essential condition to successfully implement these projects.

This confirms the necessity – outlined by an extensive body of literature (Vissers 1998, Haraden and Resar 2004, Litvak et al. 2005, Walley and Steyn 2006, Villa et al. 2014) – to eliminate, within the healthcare delivery organizations, the so called artificial variability through organizational strategies such as better scheduling and capacity management systems or the introduction of clinical pathways to standardize the clinical decision making process. Reductions in products’ variety and higher levels of process standardization should allow relevant improvements along the whole healthcare supply chain.

Furthermore, in terms of enabling conditions, the study confirms some robust findings found in the scientific literature (cfr. Infra) about the relevance of (i) top management commitment and (ii) strategic relevance of the logistical function. However, the results of the study do not really clarify what specific type of organizational model actually favors the strategic relevance of this function.

A final interesting finding is the presence of different respondents’ patterns on the basis of the institutional nature of the organization, particularly Local Health Authorities perceive less the benefits and more the barriers linked to this type of projects. This is due to the fact that LHAs – besides the publicness feature that characterize also public hospitals – are also required to manage supplies in the primary care settings, an area characterized by higher levels of complexity that would deserve more attention by both academics and practitioners.

Abstract

This paper examines the interaction between shared resources, collaboration and deliberate flow in healthcare processes. The research design was a single in-depth case study of the adoption of the acute stroke care pathway in a UK hospital. Our findings clearly show the multifaceted nature of the process. Variations in deliberate process flow are also driven by resource sharing and active collaboration among professionals. Additionally, professional autonomy should be seen as an extra process dependency. Failing to consider the multifaceted nature of the process the implementation of coordination mechanisms is contested, creating further issues to the process.

Keywords: Operations Management, Process Dependencies, Healthcare

Introduction

Motivated by the implementation of standardized processes in professional settings, we examine the interaction between three different phenomena; process flow, shared resources and collaboration. The paper takes as its point of departure the simple observation that there is an over emphasis on flow dependency in the world of process design; particularly healthcare operations. As Bo et al. (2018) recently note, “[m]ost operations management textbooks use the following simple approximation to illustrate the computation of the capacity of a process: the capacity of each resource is first calculated by examining that resource in isolation; process capacity is then
defined as the smallest among the capacities of the resources, that is, bottleneck capacity.” Yet, recent literature judges the validity of this traditional capacity analysis for collaborative networks based on conventional bottleneck analysis (Bo et al., 2018). As Malone and Crowston (1994) articulate in their paper, there are actually multiple forms of opposed process dependency, including sharing and fit dependencies. A point reinforced by Gurvich and Van Mieghem (2013), where they describe how, in the presence of collaboration and multitasking, this “bottleneck formula” can be inaccurate. In sum, if interactions between flow, sharing and fit dependencies are unavoidable (see figure 1), what do we know about the characteristics of these interactions and how operations respond to their consequences?

We address the gap identified above, by investigating the implementation of a nationally standardized acute stroke care pathway in a healthcare setting. Care pathways are interdisciplinary care plans that summarise the optimal sequencing and timing of interventions for patients with a particular diagnosis, procedure or symptom (Campbell et al., 1998). These are introduced in healthcare organisations to improve both effectiveness and efficiency of the organization. Once deployed (or once it moved from in vitro to in vivo) processes no longer exist in isolation, but confront with the need to interact and share resources with a range of other activities and indeed other specific care pathways (Gurvich and Van Mieghem, 2013; Drupsteen, van der Vaart and Van Donk, 2016). Therefore, from an operational point of view, this efficiency may decrease when multiple pathways are united and combined in an entire healthcare setting.

Intriguingly, although there have been exhortations to carefully considering the interactions between related pathways and some wider recognition of the need for a systematic approach to process (Smart, Maddern and Maull, 2009), the broader question of interacting dependency logics remains under-explored in (Healthcare) operations management (OM) and leads to the motivating research questions for this paper:

RQ1. How do different process dependencies interact (1a: flow-share; 1b: flow-fit; 1c: share-fit)?
RQ2. What are the managerial responses to the effects of these interactions?

**Theoretical Framework and development of the conceptual model**

The literature provides some guidance when it comes to factors that can explain the interaction among process dependencies. Figure 2 illustrates the conceptual model of our study.
Flow - Shared dependencies
Capacity utilization is an important variable that affects patient flow performance. Lack of resources and the associated organisational staffing model impacts the efficiency and effectiveness of workers, undermining flow performance. Tucker et al. (2004) found that staffing model entails a situation where healthcare practitioners may be working intensively and without respite, whilst providing little care for patients, and may be delaying care processes, creating unnecessary steps or making clinical errors. In such circumstances, rather than eliminating expenses as desired, inadequate staffing resources add costs.

Additionally, organisation’s resource management impacts communication among professionals. In acute care, communication often takes place in a busy and time-limited setting, challenging the professional’s ability to exchange timely and accurate information when this is necessary (Dobrzykowski, McFadden and Vonderembse, 2016). For example, Vargas et al. (2015) found that inadequate staffing level led to an increase of professionals’ workload and consequently limited time available to make use the communication methods; provide sufficient if not any information on the patient referral forms. Similarly, Radaelli et al. (2015) noted that increases in practitioners’ workload affected the amount of time and degree of resources that staff can devote to exchanging information and sharing knowledge, negatively impacting process performance.

However, a deficit in communication of professionals can cause ineffective care of the patients and increase of medical costs. Breakdowns in flow of processes and the ineffective administrative information exchange, can result in confusion regarding treatment plans, duplicative testing, discrepancies in medications, and missed physician follow-up, increased length of stay, ultimately leading to fragmented care and patient dissatisfaction (Vargas et al., 2015)

Flow – Fit dependencies
Patient flow issues have been studied both from scholars in the operations research and operations management field (Villa et al., 2014). Our study is built upon insights from the second stream of literature. We adopt the concept used by other authors (Campbell et a., 1998; Durpsteen et al., 2013) of the process as a structured multidisciplinary plan, which details that essential optimal sequence and timing of interventions of patients with a specific clinical problem. OM scholars recognize that part of patient flow variation may stem from patients’ characteristics and needs (Litvak et al., 2005). Although some processes, such as CT scans, can be relatively standardised, new tasks are evolved based on individual patients’ needs (Nembhard et al. 2009) making
information exchange among professionals vital to enable efficient and timely decision-making (Gittell and Weiss, 2004). Authors explain that hospital organisational and structural characteristics such as information technology (Durpsteen et al. 2016), hospital size and layout (Pagell et al., 2015) are sources of communication issues among professionals. Lahiri and Seidmann (2012) found that lack of medical information exchange facilities leads to professionals timely gathering of medical information facilitates and thus, timely delivery of time-critical services. Durpsteen et al. (2016) and Pagell (2004) note that organisational layouts inhibited informal information sharing among professionals found to enhance process integration. Some authors note that part of the variation is due to the fact that multiple professionals with different knowledge and skills are involved in the process making accurate and timely communication between them challenging (Nembhard et al., 2009; Dobrzykowski and Tarafdar, 2015). Relational resources of professionals have been found to overcome such professionals and organisational boundaries, supporting information exchange among them (Gitell et al., 2011; Nembhard et al., 2009; Dobrzykowski and Tarafdar, 2015).

Shared – Flow dependencies
Although the deployment of (physical) resources is covered in the HOM literature (Villa., 2009; Brand et al., 2005; Stirman et al., 2012), extant theory lacks significant explanation of how these resources are allocated and shared when they interact with multiple standardised processes (i.e. with specific resource requirements – outside of traditional professional judgement – for resource use) (Durpsteen et al., 2016). One explanation found in the literature was the political dimension of resourcing (Grove et al., 2010). Drupsteen et al. (2016) report that emphasis on resource utilisation and the particular performance requirements of the relevant departments creates a battle between the department which supplies the particular resource and the healthcare delivery departments’ need for access to the resource. This resulted in process timeliness and capacity issues. Although this is an important insight of how shared resources impact the capacity of the process, there is still need for OM scholars to explore this healthcare settings.

Fit – Flow interaction
Simultaneous collaboration among healthcare professionals has been studied from numerous scholars in HOM literature (Gurvieh and Van Mieghem, 2015; Senot et al., 2016; Dobriyskowsky et al., 2016; Avgerinos et al., 2017). By virtue of control of their specialized knowledge, professionals are given ultimate authority over their work practice (Nembhard et al. 2009) to make decisions independently and decide the principles of their own work activities. Recognizing this characteristic of professional work, OM scholars focus on understanding the different dynamics that can explain and subsequently improve team performance in a professional setting (e.g. see Senot et al., 2016 and Avgerinos et al. 2017 and the relevant references). Incongruity in professionals’ understanding and knowledge regarding the process associated with individual agency, was stated as a barrier to team performance. Pagell et al. (2015) note that while all the healthcare professions share a common goal i.e. caring for the patient, they have different knowledge and understanding of the process, which can lead to divergences on the approach to delivering care (Pagell et al., 2015; Senot et al., 2016).

Recently, Avgerinos and Gokpinar (2017) showed that the existence of a pair with very low shared experience, compared to the average familiarity of the team may act as a bottleneck for the whole team’s operation, resulting in lower productivity performance. A number of other studies, have suggested a positive effect of previous collaboration experience among professionals on team performance (Edmondson, Bohmer and Pisano, 2001) through the development of transactive
Managing multiple dependencies

In order to manage multiple dependencies healthcare organisations use planning coordination mechanisms. These imply the alignment of actions of interdependent actors beforehand, by suggesting behaviors that should be followed by the actors in order to coordinate the process. In healthcare settings these take the form of process artefacts, physical manifestations of the organisational processes in documents or software by which managers try to promote pathway knowledge - constrain, coordinate, control and improve work practices (Greenhalgh, 2008). Numerous scholars have shown how healthcare professionals use artefacts to enhance their cognitive work and develop shared understandings regarding the nature of their work (Nicolini et al. 2012; Mura et al., 2015), such as to align and synchronize their work, as well as produce compatible outcomes.

Additionally, professional roles of monitoring agents such as departmental coordinators, team leaders or specialist nurses are developed in an attempt to react to changes in the relevant information resources or the environment, fuse the appropriate information, and notify the work coordination and collaboration processes. Mintzberg (1979) refers to it as the coordination mechanisms of direct supervision while Gittell et al. (2002) as boundary spanners.

Recognizing the dynamic nature of healthcare processes, the involvement and interdependence of different professional groups with various knowledge and skills, hospitals adopt also less formal and more implicit mechanisms to manage dependencies. When plans and routines change, or when these are no longer appropriate to the task, or when the tasks have has very little or no routine aspects, formal coordination mechanisms are less effective because dependencies can no longer be managed in a programmed way. Recent literature (Gittel, 2002; Dobrzykowski and Tarafdar, 2015;2016; Pagell et al, 2015; Sting and Loch, 2016) defines the importance of professionals’ relational resources as implicit mechanisms to manage process dependencies. For example, Dobrzykowski and Taraʃdar (2015) showed that social interaction ties of professionals are vital element of the formal processes for information exchange in healthcare settings. When professionals have a shared knowledge on the process, share the same goals and trust the work of each other they act in support of the goals of the whole process (Gittel, 2011; Baker, 2001; Haque, 2010; Gittel, 2011; Dobrzykowski and Taraʃdar, 2015).

Methodology

The research was carried out in a medium-sized UK hospital (565 beds, approx. 5000 staff). Our unit of analysis is the acute stroke care pathway. We chose to focus on acute stroke care partly because stroke is the third most common cause of death and of complex disability in the UK and worldwide. Moreover, the acute stroke care pathway was selected because stroke patients are
relatively inactive in the process, which allows us to capture variability factors related to systems and processes.

Stroke care is consisted from five key stages: patients arrive to the hospital by ambulance or by own means from home or as general practice (GP) referrals, they receive an initial assessment in emergency department (ED), have a diagnostic computerised tomography (CT scan) in the radiology department (RD), then return back to ED where a decision on their diagnosis and treatment plan is made. Finally, if they are diagnosed with stroke they are admitted to an acute stroke unit (ASU) to receive further specialised stroke care. Several professionals located in these groups participate in the process.

Data collection and analysis
Our research is based on four data sources: semi-structured interviews, non-participant observations, archival documents and secondary individual patient data. Data were collected during an eleven-month period, from March 2015 to February 2016 and the process was divided in five different phases.

In the first phase we conducted 15 interviews to familiarise ourselves with the stroke care process and the role of everyone in it. The interviews were all recorded and typically lasted 30-45 minutes on average, were loosely structured using a topic guide that covered: ideal stroke care process, causal factors of its variation, and suggestions for improvement options. Additionally, we analysed several formal and informal process documents and non-participant observations. In the second phase, we combined all of the collected data and developed a first draft of a detailed process map, using a horizontal swim lane flow chart. We followed this up, in the third phase, by conducting 8 interviews with medical staff to evaluate this process map and in parallel, we continued conducting non-participant observations. Field observations took place across several locations, including the ED, the ASU, RD and the emergency medical assessment unit (MAU).

In the fourth phase, we conducted an additional 19 semi-structured interviews. These interviews followed the framework of a modified Sequential Incident Technique (SIT), which has been used in the literature to unravel irregularities, limitations and bottlenecks associated with a process (Stauss and Weinlich, 1997). We used the process map that was developed in the previous phases-walking through this with the participants, noting any stated variations to it, and the main causal factors and issues behind variations. Participants were also asked to describe in detail any specific incident, when possible, to illustrate their statements. And, at the last, fifth stage, we organised a workshop inviting all care professionals involved in the pathway (16 attended). The attendance of 16 people in total comprised of several practitioners involved in the process. The whole workshop lasted one and a half hours, beginning with a 30-minute presentation outlining the background, methodology and findings of the study, and followed by an informal discussion between the researcher and the participants for around an hour. During this discussion, the researcher was asked by the participants to clarify and explain some of the findings, and suggestions and ideas for improvement were discussed.

In total our qualitative data collection comprised of 192.5 hours of non-participant observations, 42 formal interviews and detailed documentation of 52 instances of patients following the acute stroke care pathway.
Findings

Flow – Shared dependencies

Our analysis shows that, in line with classic OM logic, variation from ‘standardized work’ is driven in part by flow dependency considerations. In many instances, we observed that lack of professionals to communicate in an accurate and timely manner, resulted in flow process issues: “Many times, not having an ED or stroke consultant available with you to assess the patient and make that decision can delay the process. I can assess the patient, but I cannot make the final decision on my own” (SNP2). We observed that such communication failures among professionals were caused due to the way that resources were managed locally. Particularly, we observed that the availability of hospital resources affected professional workloads inhibiting their ability to carry out tasks: “it is the workload of the doctors ... they have to prioritise other things over accompanying the patient to the scanner” (ED2). When practitioners were unable to carry out their tasks, in order to mitigate the variation and to proceed with the pathway, some tasks were undertaken by other available and eligible staff involved in the pathway, resulting in issues with their workload and process flow.

Additionally, resources specifically dedicated to stroke care (i.e. stroke nurses and beds) were also frequently used to support the function of other hospital departments: “Usually there are problems in finding an ASU bed. There is no bed available and you try to sort out a bed, and if there is no way to locate a bed, this will cause significant delays” (Stroke nurse). When professionals were busy, the exchange of administrative and medical information – important for the facilitation of the pathway – varied and created process communication issues: “Sometimes there is a delay because we (the Radiographers) forgot to tell the Radiologist. When we get very busy and the communication site is lost” (SR1). Such issues were more pronounced between individuals located with considerable distances between them.

Flow – Fit dependencies

Similarly, we noted that, none of the medical practitioners shared precisely the same understanding of the care process. Practitioners tend to have different medical and coordination understanding regarding the stroke care pathway, undermining process flow: “I feel that some of the ED doctors do not agree with the stroke doctors. Thus, when it comes to decision making, there are some cooperation issues there, this delays the process.”

Physical distance among members of professional groups constrained information exchange and development of a shared process (Radaelli, Lettieri and Masella, 2015). For example, the ED nurses who had frequent interaction with the SNPs were observed to always inform them for the arrival of stroke patient in the ED. Similarly, SNPs worked more efficiently with ED staff compared to the stroke doctors. SNPs had significantly more interaction with the ED staff, and consequently, were more familiar with their working approach. In contrast, the stroke doctors who had limited interaction with the ED staff and environment found it more difficult to adapt to the ED environment when they needed to go and assess the patient: “I do not know how they work down there. It is not clear to me like in my department where I know who manages which bed all the time. That might cause issues to the communication because it is not clear with who to communicate” (Stroke Doctor).

Relational resources of professionals, positively related with their location were found to support their communication. SNPs needed to communicate with the stroke team, they called practitioners directly on their personal phone numbers, and thus communicated more quickly. In cases where the SNPs could not contact a colleague directly, they would contact an alternative member of the
team whom they knew would be able to assist them. In contrast, in the event of requiring information from a colleague in a different practitioner group, the SNPs had to use the formal and highly impersonal hospital communication system (the bleep); which caused delays.

We found that compliance with the stroke care pathway was strongly associated with individual professionals’ interest and knowledge: “I think again nursing wise it depends on who is on. It matters who is there, I think nurse Y who is involved in many projects related to stroke and she is aware of what the priorities are. The level of awareness of importance and priorities of stroke is patchier for the nurses in the ED.”

Moreover, pathway artefacts (physical representations of processes such as protocols, scripts, process diagrams etc.) it was one more representation of the diverse knowledge, understanding and interest of professionals on stroke care. We found that even for a single standard pathway implemented in a single hospital, there were 9 different versions of it in different forms: 4 flow diagrams, 3 scripts and a combination of script and flow diagram. Each department involved had its own protocols employed to carry out the work, which viewed as problematic by clinical staff, creating variation in their performances: “We have no clear protocol shared between us which complicates our work” (SNP2).

We found that guidelines and protocols are most frequently developed and used by experts in each professional group, and they are used by people with varying levels of expertise (Patel, Arocha and Kaufman, 2001). However, there were continuous inherent conflicts between the autonomy and improvisational tendencies of professionals that caused the development of alternative pathways of routine practice challenging their collaboration. Particularly, the absence of sufficiently detailed information (both medical and coordination), within the pathway documents hampered the practitioners’ ability to efficiently and effectively carry out their tasks: “There are some patients that have coordination problems that are not easily picked up by the medical test that we are using. So the paramedics are not alerted to their condition. And do not recognise that they have had a stroke.” (ED 2).

**Share – Fit dependencies**
Misalignment of the pathway targets with the other pre-existing portfolio targets and goals, induces ‘quasi-competition’ of the pathway with other hospital treatments and pathways for the necessary resources: “We have so many KPIs and these are conflicting” (SR1). Particularly, we observed that different performance requirements within the departments delivering care processes created a conflict of interest between the department which supplied the particular resource and the demanding departments’ (customer) need for the use of the resource: “ED has other competing priorities. So, in order to meet the 4hr you have to transfer the patient out of the ED to the ward. So, that will come ahead in theory of the stroke.” (SNP 2)

Individual care professionals create variation in the care tasks and make decisions regarding which type of care is needed or is the priority, resulting in a negative effect both for the pathway (allocation of resources) and the patients: “So, from the ED nurses the comments that you get is that: “You are not the only priority”. Which proves exactly that there are multiple priorities. ED knows that stroke care is important but they do not know how to prioritise it really. That is why they need us; that is why they leave it to us.” (SNP 3).

**Discussion**
The research suggests three areas where there are novel theoretical (OM) insights and specific implications for both healthcare practitioners and policy makers. Firstly, for theory, stressing the
need for a multi-faceted/level notion of process is a key insight. In considering how the pathway works in practice the research revealed ample evidence of a common feature of flow dependency, communication failures among professionals. In the hospital setting, geographical (i.e. it is an old, small site) and organisation structural constraints (i.e. different departments have common locations, based in large part on history) information exchange between caregivers was challenged. This had an impact on the timing and use of resources across the mandated pathway. It also hindered the development of trust/social capital, etc. which enhance professional collaboration and, consequently, support the flow. The study reinforced this observation, highlighting that those individuals who had superior social capital (perhaps the result of frequent interaction, etc.) were able to collaborate better, adjust in a timelier fashion to effectively manage any unexpected variation and to minimise the impact on interdependent flow.

A series of observations indicated that the pathway simultaneously exhibits additional dependencies that interact between them affecting its operational performance. Stroke care pathway is also a sharing resource dependency. Although OM researchers have highlighted the negative impact of variability in care, this study shows that attempts to blindly implement standardised work can also create capacity issues. Fragmentation of capacity creates continuous interruptions in the process and causes a negative effect both on its effectiveness (i.e. accuracy in decision making) and efficiency (i.e. timeliness and use of resources). Extending the discussion of shared resources to the broader question of how a hospital reconciles – or fits - all its different care pathways (explicit and implicit, formal and informal) together in a coherent way. The research confirms that such fit dependency issues were not considered in the pathway design; made manifest in a wide range of hospital KPIs, flow charts (and other artefacts) diagnostic disputes and the basic geography of the hospital creating variation to the process. Individual care professionals create variation in the care tasks and make decisions regarding which type of care is needed or is the priority, or how to practice performance measurement.

The study also highlights the political dimension of resourcing. There is a direct connection between pathway adoption, professional responsibilities/judgements, resource competition, and consequently political dynamics. This potentially unstable dynamic system is underexplored in the HOM literature. Therefore, even if the care pathway approach is a rational attempt to solve the flow dependency (integration) puzzle, in attempting to address the fit dependencies, there was a strong and continuous stress on performance measurement in parallel (Power, 1997) which autonomous professionals can easily undermine the game.

Second, the study illustrates the role that professionals play in how the process dependencies are managed and that they are much more than just co-ordinators or pilots (Lewis and Brown, 2012). We show that professional autonomy is equally present in the reconciliation of shared resources, fit and flow dependencies. A carefully designed pathway rapidly became incoherent as it encountered resource-sharing decisions made by autonomous medical staff and managers. Autonomy frequently led to minimally shared mental models of care, perspectives on the best interests of the patient, and (often highly dysfunctional) competition between individuals and groups causing a negative effect both on its effectiveness (i.e. accuracy in decision making) and efficiency (i.e. timeliness and use of resources).

Third, this study illustrates how not considering the multifaceted nature of the process, the performance of used coordination mechanisms is contested. Particularly, our findings show how a pathway artefact is a zone of two types of autonomy: that of the modeller who designs it and the professionals who use it. Even if artefacts are designed by the hospital managers to coordinate flow
and standardise professional work, these are only aspect of the design process. The artefacts are then used by autonomous professionals who design and redesign the process differently every time they follow it. Professionals generally work with heuristics and rules. Professionals do not learn only from flow charts, but they study, see and apply, and learn from each other. Consequently, although pathway artefacts represent flow dependency, through their failure to recognise the professional autonomy associated with knowledge specialisation, their role as professional boundary spanners is tested.

Numerous scholars who study the role of artefacts in healthcare practice, have shown how healthcare professionals use artefacts to enhance their cognitive work and develop shared understandings regarding the nature of their work (Nicolini et al. 2012; Mura et al., 2015). Professional expertise depends on, and develops through, the mediatory work of many artefacts that professionals use to carry out their work. However, the findings of this study the findings reveal that even for a single standard pathway implemented in a single hospital, there were multiple pathway artefacts. Visual representations were different for different professional groups: ASU stroke team, ED staff and Radiology department. The interesting question is the extent to which this is simply a manifestation/representation of ingrained points of difference, or whether the multiple pathway artefacts actually serve to exacerbate these performative differences of the process. Individuals from the different practitioners’ groups shared diverse competence on stroke care and the absence of sufficiently accurate (both medical and coordination); information undermined the exchange of correct and timely information and decision-making. For example, not all the ED staff knew how to thrombolysie patients and the absence of such procedural information in the process artefacts resulted in breakdowns of the care process.

Similarly, to the process artefacts, the creation of a process ‘pilot’ role (the Stroke Nurse Practitioner) to help navigate patients along the pathway is one more organisational mechanism for managing process interactions. We found that such mechanism is indeed effective for coping with the sharing and fit interactions, but at the same time the successful implementation of such initiative was influenced from sharing and fit dependency issues.

On one hand, this study confirms previous findings that the specialised nurses have a positive effect on the efficiency and effectiveness of the process (……). Particularly, we observed that due to their role and ability to interact with all the professionals in the process, SNPs were provided enough information and understanding about the working approach of the other colleagues and the system to predict their future behaviours. Thus, being capable enough to make and set accurate judgments and expectations accordingly, such as to accommodate variations in colleagues’ performances and to support them when needed, which would otherwise negatively affect the process. Fitzgerald et al. (2007) call this ‘theory of mind’; “the ability of individuals to understand others’ behaviours, mental states and intentions, and use this knowledge to advantage”. On the other hand, we found that shared dependency issues (i.e. practitioners not being available to carry their tasks) led to SNPs increase of workload and consequently created both flow and fit issues. SNPs had limited/no power in controlling the competence/ interests and associated actions of other practitioners, resulting in staff blurring issues, pathway timeliness issues and inaccurate decision-making. Again, this is an indication that financial resources and the associated organizational scale affects the implementation of process management initiatives in SMEs (Alkoharaif et al., 2018).

Abstract

This paper considers how the manufacturing origins of lean management (LM) and theory of constraints (TOC) characterize distinct flow management approaches before evaluating how they have been effectively applied to improve patient flow. Both of these approaches originated in distinct environments and this multi-case research explores how the assumptions and associated practices transfer to healthcare. The case analysis considers complex flow across health and social care including outpatient, community and mental health. The paper focuses on how the management signaling tools of Kanban and time buffer management have been interpreted, identifying the common theoretical assumptions and implications on practice.

Keywords: Health and Social Care, Lean Management, Theory of Constraints

Introduction

Worldwide healthcare service providers have been exposed to growing pressures to simultaneously minimise operational costs and improve the access and quality of care they deliver. Changing demographics and increasing demands facing healthcare delivery systems have created more complex pathways to access healthcare services and necessitated the integration of social care to enable safe discharge of patients (Alderwick et al., 2015). The growing pressures within health and social care delivery indicate operational challenges that reflect the primary need to synchronise capacity and demand in enabling patient flow (Karakusevic, 2016; Tabish and Syed, 2015).

According to Olsson and Aronsson (2015), many healthcare services across the globe have implemented process improvement approaches like lean management (LM) and the theory of constraints (TOC) that focus on flow as a proxy for system productivity. However, there is a tendency to adopt one or other approaches irrespective of the healthcare environment with little consideration of how these manufacturing approaches might be theoretically developed to meet the needs of different health and social care environments. Where LM and TOC have been applied, there have been mixed results regarding the success and assumptions underlying the application of such approaches to healthcare (Blackmore and Kaplan, 2016: Radnor et al., 2012; Stratton and Knight, 2010).
This research aims to broaden academic understanding of how established flow management approaches have been developed to meet the distinct conditions within the wider healthcare system, with specific reference to the origins of LM and TOC. Three questions provide focus for this largely exploratory case research:

- How can LM and TOC approaches be effectively applied to improve the patient flow across health and social care?
- Why do these management approaches work better in different health and social care environments?
- What are the assumptions underpinning their effective use?

**Literature**

Improving patient flow is seen as a major factor in improving hospital performance (Litvak, 2009), as flow performance is an important aspect of organizational performance. The changing demographics and increasing demands faced by the healthcare delivery systems have created complex pathways to accessing healthcare and have necessitated the integration of health and social care to support the safe discharge of patients (Alderwick et al., 2015). Considering the current budget faced by the NHS, the healthcare delivery system’s current capacity challenges, and that over 40 per cent of the NHS England’s budget is spent on older people, the importance of patient flow between acute services, primary care and social care in the NHS and the UK healthcare delivery system can never be overlooked (Karakusevic, 2016; Robineau, 2016). However, evidence from manufacturing suggests that enabling flow based management is not easy due as the the different elements in the healthcare system are directed, supported, controlled and structured in silos that fight the flow imperative (Fillingham et al., 2016). Delayed transfer is indicative of this deeper failure of the system to provide the right care at the right place and at the right time (Humphries, 2017). Therefore, this literature review firstly considers the paradigm shift in thinking associated with manufacture and particularly the emergence of two distinct approaches, namely LM and TOC. The influence of these approaches on flow management in healthcare is then explored alongside the development of healthcare specific flow management approaches.

**System flow thinking**

The adoption of a systems approach to managing operations is commonly associated with managing variability and flow as opposed to local optimization based on cost and efficiency. These developments were sustained because they were accompanied by seminal innovations that offered a practical means of embracing the management of variability and flow across the delivery system. This is illustrated by Ford’s physical flow lines (1926), Shewhart’s (1931) statistical process control, Ohno’s (1988) kanban control and Goldratt’s (1999) time buffer management (TBM). These signaling tools provided a means for management to adopt a systems perspective that guided the organization in enhancing value creation.

Skinner (1969) introduced the concept of operations strategy by highlighting the limitations of local sub-optimisation based on cost and efficiency that dominated operations management practice. He acknowledged performance trade-offs and the need to focus, separating out delivery system design to meet distinct environmental factors which was subsequently allied with variation and volume (Hayes and Wheelwright, 1979). Each of these developments were concerned with adopting a longer term systems approach to managing operations that is now embraced in operations theory; as in cumulative
capability (Ferdows and de Meyer, 1990), Performance frontiers and swift and even flow (Schmenner and Swink, 1998).

All of these developments have had wide ranging influence on operations practice but two in particular have contributed to flow management in health and social care, that of LM and TOC.

The TPS was clearly designed to meet the needs of Toyota and the relatively stable demand and standard pathway design in a dedicated facility. This resulted in a number of tools and techniques concerned with reducing variability and improving flow that as we shall discuss are linked through the Kanban signaling tool.

TOC was designed with a broader mission but initially aimed at the make to order (MTO) environments typified by low volume aerospace including repair and overhaul. This more generalized concern resulted in the underlying flow issues being explored and with it the conflict between flow and cost/efficiency. Goldratt (1999; 2009) more explicitly identified the importance of capacity buffering and the role of control points in the management of complex systems. Time Buffer management (TBM) emerges as a central signaling tool in all the TOC applications and has more recently been developed to meet the specific needs of patient flow across health and social care.

Kanban

Kanban which means signal is aptly named and Ohno consider it to be key to the success of the TPS in bringing together the six rules/fuctions of Kanban (Ohno, 1988:30).

‘In reality practicing these rules [the six rules of kanban] mean nothing less than adopting the Toyota Production System as the management system of the whole company.’ (Ohno, 1988:41)

This tool was more flexible in use than Ford’s flow line but still needed the flow path to be precisely defined and direct (Spears and Bowen, 1999:98) ensuring that variability can be continually exposed and addressed through the systematic reduction of inventory (Junior and Filho, 2010). The many other tools are effectively used to support this ongoing process that sustains the TPS.

Time Buffer Management

Kanban signaling was too structured to meet the wide ranging processing needs of MTO and engineer to order (ETO) but it was still necessary to control and improve work flow across these more complex pathways. Goldratt adopted the concept of aggregated time buffers focused on control points, acknowledging the need to more effectively manage the excess capacity that characterizes this level of complexity and termed this time buffer management (TBM) (Goldratt, 2009).

Applying System Flow Thinking to health and social care

Let us now consider how LM and TOC thinking have been directly and indirectly applied to healthcare flow management.

Lean Management (LM)

As in manufacturing practice has led academic theory in improving patient flow with hospitals taking the lead (Graban, 2010) and notable hospitals leading the application of LM including The Pittsburgh Way (Grunden, 2007), The Royal Bolton Hospital (Fillingham, 2007) and Virginia Mason Medical Centre (Kenney, 2010). However, much of this has
involved secondary processes such as consumables, pharmacy and test procedures rather than patient flow and although there have been significant improvements in patient flows these are typically associated with the redesign of medical pathways (Fillingham, 2007). These applications are consistent with TPS LM improving flow through the redesign of the physical flow path (Hicks et al., 2015).

**Theory of Constraints (TOC)**

In addition to LM the application of TOC thinking to healthcare has been encouraged through various NHS education improvement bodies in the NHS and worldwide, typically centering on *The Goal* (1984). This guidance primarily acknowledged the role of bottleneck management and the need to focus the planning and control around constraints (limiting factors) in the delivery system. As with LM some hospitals and NHS foundation trusts in the UK and the Netherlands have at times adopted TOC as an overall management approach. Typically with the support of TOC expertise, as in the case of QFI Consulting which developed applications used by two of the case companies in this research. Prior research studies have reported on these results which is centred on the use of TBM (Umble and Umble, 2006; Stratton and Knight, 2010). A broader view of the approach is presented in *Pride and Joy* (Knight, 2014) a healthcare centred version of *The Goal* (Goldratt, 1986).

Due to the case evidence making specific reference to this healthcare based TBM the key features are covered here.

TBM is concerned with time in the manufacturing and project management applications and this is also the case in healthcare and it incorporates feature from both but in many ways taking on a simpler design. Time runs from left to right in Fig 1 which illustrates how the planned discharge date (PDD) for all patients is set based on the patients’ medical needs. This is the means of exploiting the constraint of time. Going beyond this date would result in a delay and typically today measured in the NHS by delayed transfer of care (DTOC). The vertical dotted line represents the current time, signifying a review of this patient by a multi-disciplinary team (MDT). The purpose of the TBM signaling tool is to ensure the PDD is met so avoiding any DTOC. To do this all the activities required for discharge need to be completed by this date and these activities and their expected durations are represented by horizontal lines in the Figure where each resource provider is a different colour. TBM effectively manages progress through four functions (prioritise, expedite, escalate and improve) (Stratton and Knight, 2010). The Figure is currently showing the orange activity is in the yellow indicating priority over brown and black with the blue activity is in the red which signals the need to expedite. The blue resource (e.g. occupational therapy (OT)) would see this patient on the aggregated worklist in colour order (R,Y,G) prioritizing patients based on the PDD which is subject to change. A growing number of reds and blacks signals the...
need to escalate the growing instability of the system. Buffer management meeting are held daily and monthly to address short term and longer term improvement activity.

Red 2 Green

An approach currently being widely promoted with in the NHS that acts in a similar way to TBM is called ‘red2green’. The approach is a visual management system that supports the identification of wasted time in a patient’s journey and as with TBM has been applied in both an acute and community settings to minimise internal and external delays and deliver improved patient flow (England.nhs.uk, 2019). Red days are when patients receive little or no value adding care while green days are when patients receive value adding care, advancing their path towards discharge.

The red and green day process uses ward improvement boards to link flow, safety and reliability with visual demonstration (Improvement.nhs.uk, 2019). Using ward level metrics, the process identifies what limits (constrains) a wards ability to convert red days to green days and proactively manages these at ward rounds. Where improved solutions are not immediately available there is an escalation process where processes are put in place to actively manage these limitations. The top five constraints are reviewed by senior operational managers and are formalized in a local improvement plans.

SAFER patient flow bundle

Again, there are clear similarities with The SAFER patient flow bundle aims to promote engagement and continuous improvement through combining five elements of best practice: Senior review; expected discharge date and clinical criteria for discharge for all patients; flow of patients at the earliest opportunity; early discharge; and senior review for patients for management and discharge decisions (Improvement.nhs.uk., 2019). This SAFER patient flow bundle is considered to work more effectively when implemented with the Red2Green days approach and when all five elements are implemented there are considered to be cumulative benefits (England.nhs.uk, 2019).

Design/methodology/approach

This ongoing research adopted a multi-case approach to address the research questions for the study involving over 30 interviews and the selective use of documentation and observation in five case studies across three NHS Trusts. These involve a range of delivery systems where there has been a transformative approach to improving patient flow. The first three cases were selected to exemplify specific LM and TOC implementations with other two chosen in line with theoretical sampling logic in the light of the earlier case findings.

The cases incorporate acute and rehabilitation hospital care, social care, outpatient services and GP led community care and community mental health. Data were gathered through semi-structured interviews, observation and documentary evidence comparing performance in relation to the interventions over time. The interviewees were selected due to their managerial or operational involvement together with external consultants where relevant, with interviews taking between 40 and 90 minutes. The interviews covered several questions on the process, description of original design, process issues in the original design, the recorded changes and results achieved.
Findings

The Speech and Language Therapy

This NHS case provides speech and language therapy for children between 0 and 18 years of age with more specific and complex needs. Prior to the intervention there were complaints about the growing waiting lists that breached the NHS 13 week assessment and 18 week start of treatment targets. An external consultancy was brought in to provide a TOC solution. They found a lack of management visibility with therapists tending to work in isolation managing their own patient lists. Figure 2 shows the patient journey within the speech and language therapy prior to the intervention. To address this issue, the consults established a new process that prioritized patient appointments in one aggregated list on a first in first out approach with a two week initial assessment target. At that meeting they also planned the whole package of care typically involving multiple therapy appointments effectively resulting in a PDD.

Figure 3 illustrate the new process where there was a two week internal target for the initial assessment which was achieved through short term additional capacity. This system was supported by a rudimentary spreadsheet based buffer management system due to policy restrictions on the introduction of TBM software.

Adult Nursing Community Services

This LM case involved nurses, OTs, support workers, physiotherapists and community matrons, who focus on assisting people aged 18 and above to live independently and accelerating their discharge from hospital. Before the intervention here were no formal processes and the processes lacked standardization resulting in poor productivity and patient facing time while increasing waste as non-value adding activities consumed the nursing staff’s time. The intervention involved the widely adopted LM based productive series with significant improvement in some communities. This included the application of 5S and other tools in the workplace, creating a clean, safe and orderly environment to work in. Better process orientation resulting in improved control of inventory and waste elimination. The 5S created the platform for efficient production planning and directed the Trust’s focus to structurally reorganise the operation process to increase patient facing time and productivity.
Although the efforts were based on a national agenda to improve service delivery the improvements recorded were realised only in some community services and did not reflect on the overall service across the county. This widely applied LM practice has provided significant improvements across the country but the improvements are inherently local and dependent on local management practice. As with Kaizen Blitz projects these local redesign activities are difficult to sustain (Radnor et al., 2012) arguably without an overarching management signaling tool.

Community Hospital
This NHS Foundation Trust is an integrated community healthcare trust that provides health services to both children and families, patients with learning disabilities, substance misuse needs and mental health problems. This is a long standing TOC application including the adoption of software to support patient flow and the application of the TBM. This TOC approach was introduced 12 community hospitals although some have since been closed. The system had been in operations 9 years and the initial average length of stay (LOS) was reduced from over 60 days to around 20 days on average today.

“Eight or nine years ago, the average length of stay would have been 60 plus days and I’m delighted to say that now we report exceptions on the basis of any length of stay over 20 days.” (P01)

The system design is consistent with the TBM approach presented in Fig 1. And the patient discharge date is determined together with a plan on arrival.

“One really important thing that has been embedded in the process is that you start planning someone’s discharge from the moment they arrive.”

The Trust results indicate that prior to the implementation of this Jonah system, they were not aware of any barriers to flow within the system.

“So before Jonah I was not aware of there being any central visibility and understanding whether flow is efficient or whether there are any barriers.”

“One thing that Jonah did was to promote clarity about what we are trying to achieve and how we are trying to do it.....”

The Trust initially adopted this TOC based system due to the need to replace hospitals and reduce the number of beds and this process of reducing LOS and synchronizing transfer of care with social care has proved to be very effective. The system is very effective at supporting the management of DToC and they are some of the lowest in the UK.

Consistent with the functions of TBM the weekly top delay meeting focuses on reviewing patients who are in the red zone or already a delayed transfer. These meetings are multi-disciplinary and attended by general managers and social workers. As illustrated in Figure 4, waiting for care packages is the typical major reason for delay. This Pareto data provided by the Jonah software provides focused data to support these meetings.

Identifying and overcoming the principal cause of delay across health and social care provides a systematic process
that sustains the continuous improvement culture. It is interesting to note that the Trust retain Jonah even with the need to duplicate data input as the centralized System One, now rolled out across the NHS does not provide the data in a form suited to managing patient flow.

**Mental health case**
This case is still in progress and is showing significant improvements primarily through adopting new flow management rules akin to SAFER patient flow and Red2Green introduced earlier. This, as discussed embraces many of the same features as TBM with some interesting distinctions.

**Social care housing case**
This case is also ongoing and illustrates how the local authority has gained awards for their emergency housing provision supporting the discharge of vulnerable adults from acute wards. This case is particularly interesting as it highlights the tension associated with budgetary control. This is evidence by how this very successful programme is repeatedly under review primarily due to this successful cross-functional patient flow activity falling between the local management priorities associated with localised cost control.

**Discussion / Conclusion**

- **How can LM and TOC approaches be effectively applied to improve the patient flow across health and social care?**

LM and TOC have developed distinct approaches to managing flow to meet the needs of distinct manufacturing environments but their success has resulted in flow being widely acknowledged as a proxy for system productivity. Healthcare management similarly acknowledges the importance of flow, but to what extent do the associated LM and TOC signaling tools (Kanban and BM respectively) support patient flow? TBM has been shown to be a central feature of TOC across its core manufacturing applications and the common four functions have also been shown to apply in healthcare and social care systems. Kanban is often perceived to be one of many tools aimed at reducing variability and improving flow in LM however its critical importance in sustaining flow improvement is sometimes forgotten. This is achieved in manufacturing by establishing clearly defined flow paths and this need for a clear physical path is a key distinction between TOC and LM. Therefore, where the LM redesign is narrowly defined, as in kaizen blitz activities, the isolated improvements are not linked to the wider delivery system and commonly lack this important means of sustaining the improved flow. Although the case evidence was limited in this regard the Productive Ward evidence and the use of 5S is consistent with prior research that identified this problem (Radnor et al, 2012) even though these finding challenge the subsequent evaluation (Radnor et al., 2013).

- **Why do these management approaches work better in different health and social care environments?**

LM and TOC shift the emphasis from local performance to system performance by enabling flow across the delivery system. This can be achieved by reducing variability and uncertainty which is the emphasis of LM whereas TOC is firstly concerned with changing the rules concerning the management of flow and the strategic location of buffers. Whereas LM is associated with a wide range of tools to support the reduction of variability and improving...
flow TOC essentially has one, TBM. TBM is the means of providing management signals to ensure delivery system activities subordinate to the exploitation of the system constraint. In healthcare, as in manufacture, this is ‘time’ and setting a PDD is critical to exploiting the time constraint in the healthcare environment. The 4th function of BM is to identify strategic opportunities for improvement and the LM tools are deployed to achieve this.

Although LM is associated with many tools the kanban signaling tool was key to the sustained operation of the TPS. However, its application is more operationally demanding as there needs to be clearly defined flow paths and the improvement activity is distributed rather than focused. Whereas, BM uses aggregated buffers that is more accommodating to variability and uncertainty kanban is more sensitive to flow disruptions and therefore higher performance in a well-defined delivery system.

Healthcare is characterized by a range variability and uncertainty and where there is opportunity to define the process flow tightly LM can be readily applied. This includes patient flow but these findings suggest it is more suited to elective surgery or emergency pathways that are predefined. Where the pathway is unknown, poorly defined and involves transfer of care the signaling is better suited to TBM. This was evident in the TBM solutions witnessed, including the need to subordinate the flow focus to the PDD, so synchronizing all activities around this patient, whether in outpatient or inpatient environments.

LM, deriving from the more structured TPS supports physical flow requirements to be structurally entrenched. The adoption of the 5S in the implementation of the productive toolkit at the adult nursing community represents efforts to structurally reorganise processes and ensure all resources are at the right place at the right time. This supports the establishment of flow paths through standardised processes.

More varied and uncertain environments benefit from the adoption of aggregated buffers as advocated by TBM in the Speech and Language Therapy case, moving to a central patient queue allowed more effective priority control with the centralised allocation of therapists as opposed to a locally distributed resource. This key feature allows therapists to focus on managing one queue and adopting a common priority system. The scheduling of the treatment plan at the first consultation (initial assessment appointment) is also consistent with flow management by setting a PDD, so ensuring that the number of patients in the system is kept short.

In the DCHS case the establishment of a PDD was key to enabling the other support activities to be prioritized around the patient needs and so proactively managing the threat DToC, a particular issue for the elderly with transfer between healthcare and social care providers. In this case the use of formalized software (Jonah) enables the functions of buffer management to be more effectively realized including Pareto data to support buffer management meeting seeking means of improving performance.

Table 1 Kanban and Time buffer Management assumptions
• What are the assumptions underpinning their effective use?

The assumptions underpinning kanban and TBM apply across both manufacturing and healthcare are presented in Table 1. The less restrictive assumptions underpinning TBM and therefore wider potential application is arguably supported by the wide use of TBM related developments as in SAFER - red2green, but the findings need to be discussed further.

Abstract

The paper aims to focus on systematically analysing and synthesising the extant research published on supply chain strategies (SCS) in healthcare. More specifically, the authors aim to answer three questions: “Q1 – What are the strategic intent of SCS?”, “Q2 – What are the operational measurement?” and “Q3 – What are the inhibitors factors of SCS?” Furthermore, the paper strives to address the question of how SCS can help in redesigning an efficient patients’ flow in response to face hospitals dual challenges of reducing cost whilst building the capability to accommodate growing numbers of patients with different and increasingly complex needs

Keywords: healthcare, patient flow, (Hybrid, Lean, and Agile) supply chain.
Introduction:
In response to healthcare system challenges, where limited resources are the main characteristics of the public healthcare on a global scale (Ix, 2009), redesigning of healthcare systems to deliver efficiency alongside quality care has become a demand of healthcare leaders, if not the public itself.

There has been a great deal of literature is available on supply chain management in manufacturing sector; however, little research exists on managing services especially healthcare services (Cherian et al. 2010). In healthcare, supply chain management processes have three types of flow: physical product flow, information flow and financial flow (Singh et al., 2006). In this paper, the discussed supply chains are the patients (physical product) flow through the healthcare system, such a hospital. Addressing the question of how supply chain management can help in redesign an efficient patients’ flow in healthcare organization.

This paper aims to focus on systematically analysing and synthesising the extant research published on supply chain strategies in healthcare. More specifically, the authors presented categorization of these strategies in healthcare that considers types of supply chain strategies, the strategic intents, operational measures and inhibiting factors of each strategy implementation. Furthermore, the paper strives to address the question of how supply chain strategy can help in redesigning an efficient patients flow in response to hospitals dual challenges of reducing cost whilst building the capability to accommodate growing numbers of patients with different and increasingly complex needs.

Methodology
This paper adopts a systematic or evidence-based literature review methodology based on the five-step approach developed by Tranfield et al. (2003) and Denyer and Tranfield (2009) as show in Figure 1. The advantages of the systematic literature review (SLR) approach over narrative reviews is that choices made during the literature search, selection, and analysis are reflected on and made explicit to result in a transparent and reproducible repository of knowledge.
Taking heed of advice for the conduct of structured reviews, Rousseau et al. (2008) guidance on study selection criteria in management and organizational sciences has been followed. Furthermore, as Durach et al. (2017) calls for a ‘theoretical lens on the phenomenon of interest’ to provide greater focus during the review, this study has chosen to look at patient flows from a supply chain strategy angle which fits with the research motivation as outlined in the introduction section.

To select relevant publications for review, firstly duplicates among the 11919 publications identified in the previous step were removed, which resulted in 10609 publications taken forward. Next titles and abstracts of the remaining publications were screened using a set of inclusion and exclusion criteria, which are shown in Table 1 below together with accompanying rationales for each criteria. To ensure the reliability of this process and prevent researcher bias, each of the authors independently reviewed a sample of 80 random abstracts with inclusion and exclusion choices subsequently discussed collaboratively between the three authors. This ensured that the criteria were understood and applied similarly. Subsequently the selection process based on titles and abstracts was undertaken by the first author while being consulted in borderline cases. This resulted in 10053 publications being removed from the pool.

</tbody>
</table>
Following these publication selection steps ultimately resulted in 58 publications to be selected in this review. Figure 2 below provides an overview of the different steps and how many publications were rejected or taken forward at each stage.

![Figure 2: Summary of the publication selection process](image)

**Descriptive Analysis**

It becomes apparent that research activity on supply chain management in healthcare has increased relatively steadily from 2010 onward, look at figure 3, with sparse publications prior to that year, before peaking in 2016. Given the cut-off point for the literature search in January of 2019, also shows that case studies remains the dominant research methodology in this area as 34 out of 58 publications use either a single or multiple case study approach.

![Figure 3: Number of publications and their respective methodologies across years](image)

This strong base of qualitative empirical work is juxtaposed with a smaller number of studies using a variety of quantitative approaches.

In respect to the disciplines of research field, the findings illustrated in figure 4, where the field of supply chain strategy is still immature and requires further academic investigations.
Considering the geographical location of the first authors’ institutions, a strong interest in SCM in healthcare appears to originate from the UK as being home institutions to 39% of publications’ first authors. Northern Europe and the Netherlands share their second place by accounting for 22% of publications each. A common trait among these countries may be their strong research base combined with the circumstance that healthcare has been conceived as a public rather than private good, which could ease data accessibility. The USA follows this field at (12%) of publications, with Italy accounting for (8%) and then other countries at (4%) or less, with eight countries being the origin of a single publication each.

Lastly, Figure 5 shows that 58 publications can be classified as either analysing a lean, agile, or hybrid supply chain strategy in their respective contexts. This imbalance suggests that academia has progressed further in the area of lean healthcare provision, which may be explained by the implementation of lean initiatives in healthcare before the backdrop of mounting cost pressures put on public healthcare in European countries with aging populations especially.

**Figure 4: Publication distribution regarding disciplines of research field**

**Figure 5: Number of publications adopting different supply chain strategy lenses in their healthcare contexts**

**Thematic Analysis**

Having analysed the publications descriptively, this section will report the thematic findings.
Strategic intentions of lean, agile and hybrid supply chain approaches and operational measures:
Selected publications were divided into three themes based on their adopted or analysed supply chain strategy, which were lean, agile, and hybrid.

Five strategic intents for adopting either of the strategies were synthesized from the literature, which are a) improvement in patient care, b) elimination of waste, c) improvement in hospital performance, d) improvement in employee satisfaction, and e) increased responsiveness and flexibility. While there is overlap in some areas, these five intents represent the diversity of expectations researchers and practitioners hold for lean, agile, and hybrid supply chain strategies when attempting implementation.

An initial intent is the improvement of patient outcomes. Operationally this is typically measured by looking at how fast and with which level of safety patients move through the healthcare environment, although there are also authors that look at patient’s overall quality of care (Crema & Verbano, 2016; Lillrank, et al., 2011; D’Andreamatteo ,2015). Another identified strategic intent relates to the elimination of waste – here three different perspectives emerged in the literature despite a conceptual overlap between the two in the understanding of lean strategies. One operational indicator that has been used as a proxy for the purpose of waste elimination are process times (e.g. Kollberg et al., 2006; Manos, et al., 2006; Souza, 2009; Hwang, et al., 2014; Kreindler, 2017). The second understanding of waste refers to the issue of costs; (compare Radnor and Holweg, 2012; Hwang et al., 2014; Roemeling et al., 2017). The third intent is improving hospital performance, which is measured via a variety of indicators reflecting the diverse and conflicting goals endemic to the healthcare context, of initial interest here are hopes for increases in hospital productivity as measured through its efficiency – (Jorma et al., 2016; Rahimnia and Moghadasian, 2010; Olsson and Aronsson, 2015). The fourth construct in improving the satisfaction of healthcare professionals is named by fewer authors than the previous three but can be expected to contribute to performance indirectly (Simons et al., 2017 & Rees and Gauld, 2017). These initial four constructs that were identified feature heavily in the literature on lean supply chain strategy in healthcare. It appears that the terminology and purpose of the lean approaches with a focus on speeding up processes while striving to maintain quality has been directly adopted from other industries’ successes of lean supply chain strategy. The fifth construct was only identified in papers on agile and hybrid supply chain strategies and aims to increase responsiveness and flexibility. (compare Rechel et al., 2010; Aronsson et al., 2011; Converso et al., 2015).

The inhibiting factors of lean, agile and hybrid adoption in healthcare:
Three problem area for adopting either of the strategies were highlighted from the literature, which are a) context-related, b) strategy-related, and c) human-related. These three restraining components represent the diversity of expectations researchers and practitioners hold for lean, agile, and hybrid supply chain strategies when attempting implementation. The existence of challenges in the healthcare setting may explain the slower adoption of either of supply chain strategies.

The first identified problem area while implementing a supply chain strategy is context-related, in other word, it is the area that considers the circumstances that form the setting for healthcare. (Lillrank et al, 2011; Drupsteen et al., 2013; Aronsson et al., 2011; Converso et al., 2015; Kreindler, 2017).The second problem area is strategy-related, many literature have demonstrated that ambiguous strategy for employees is one of the major inhibiting factor can face the implementation of the adopted strategy many literature (Rechel et al., 2010; D’Andreamatteo et al., 2015; Roemeling, Land and Ahaus, 2017), the second perspective is a debatable definition of waste in service sector, (see e.g.
The third problem area is human-related, four observed issues in this area are to be discussed. Firstly, the lack of leadership and communication (see more Grove et al., 2010; Al-Hyari et al., 2016; Dobrzykowski et al., 2016). A second challenge facing lean application in hospitals is the lack of employee engagement and training (see e.g. Meijboom et al., 2011; van Rossum et al., 2016; Schonberger, 2018). The third challenge is organisational culture resistant to change, Kollberg et al., (2006) specifically human-related issue regarding the embedding of change and blame culture are quite prevalent across healthcare sector which prevents lean strategy from being utilized in a systematic manner (compare Timmons et al., 2014; Lot et al., 2018).

The following in figure 6 is a summary of thematic findings represented in an archetype of supply chain strategies is healthcare context.

Conclusion:
By conducting SLR a holistic view is presented beyond reviewing individual papers, we will contribute to both the academic and professional communities. For researchers, the synthesised architype introduced is a further step in developing the understanding relating to the role of supply chain strategies in managing healthcare processes in the lens of patients flow. In the literature, lean supply chain implementation in healthcare has been discussed extensively while both agile and hybrid thinking have received little academic attention. Further research is needed to empirically test the implementation of hybrid
supply chain in healthcare, moreover, research assessing the properness of each strategy for managing patients flow is recommended which indicate the shift from the use of lean strategy as a topic of research to use agile as well as the combination of the two (i.e. hybrid).

For professionals, we will provide some managerial guidelines regarding the impact of supply chain strategies practices which should be of particular interest to hospitals’ managers, in order to tackle hospitals’ dilemma and how they can create and sustain competitive advantages in a complex and turbulent healthcare setting in addition to advice on how they can be implemented. The inhibitors factors can be used as a checklist to overcome the complexity of the hospital processes and to identify the appropriate strategy for improving performance regarding patients flow.

Abstract

Leveraging the shared economy concept of ‘access’ instead of ‘ownership’ in healthcare would facilitate in tapping latent capacity of idle medical devices, reaching to patients
without access to quality health care and higher economic savings from reduced operational inefficiencies. In our model, a hospital can either take a high-quality capacity constrained device on share from another hospital or can buy a lower quality one from the manufacturer. We study analytically when quality sharing happens and when it leads to demand cannibalisation for hospitals. We analyse the impact of price sensitivity, the quality on the socially optimal outcome and patient’s welfare.

**Keywords:** Shared economy, Healthcare, Stackelberg Game

---

**Introduction**

Global medical device industry is changing the face of the healthcare system with its highly innovative and technology-driven medical devices. The Indian government's 2017 National Health Policy envisions equitable health and well-being for all sections of the society (skpgroup, 2017). Around 69% of the Indian population lives in rural areas. Most of the region in rural areas are underserved with regards to quality medical devices. There exists an opportunity in the transformation of the Indian healthcare system, where there is a low level of penetration and adoption of advanced medical equipment. Increasing the accessibility of medical technology to improve national healthcare poises as a promising task.

In the financially stretched healthcare market, medical technology is often perceived as an expensive luxury (Davies, 2013). The high and rising prices of medical devices causes a reduction in consumers' welfare which ultimately reduces total welfare in the
The reasons for medical equipment unavailability are mainly high capital cost and lack of financing options. Low-profit margin, low-income patients mainly contribute to the high capital cost. One of the solutions is getting low-cost equipment from low-cost manufacturers, for e.g. manufacturers in SE Asia offer low-cost products targeted at Africa, which is cheaper than US OEM alternatives. However, there are cons associated like poor product fit, non-standardized parts.

Sharing economy is sharing underutilised assets to improve efficiency and sustainability. There has been a surge of sharing economy in every industry which is changing the landscape of traditional operations like, transportation (Zipcar, Lyft), entertainment (Pandora, SoundCloud), logistics (Instacart, Uber Rush), hospitality (LeftoverSwap, Feastly), consumer goods (Nichol, 2016). There’s a high demand for the collaborative economy, especially in emerging markets where it provides consumers access to services, they couldn’t traditionally afford (French, 2015). Over 1 year, 25% of UK adults used internet technologies to share resources, according to research on the collaborative economy by NESTA in 2014 (Ahmed, 2017). The sharing economy’s rise to prominence is due to the associated operational efficiencies and economic savings it introduces. Currently, two things are happening in the healthcare industry, that is actually positioning it for sharing. The number one is that the medical service providers are shifting their focus on consolidation and economies of scale because of the changes to how and how much they are paid for the provided services and the second can be attributed to the advancement in technology that is actually making sharing feasible (Mohamed, 2017). Medical surplus i.e. the usable supplies that hospitals throw out mainly accounts for the higher health care costs. Medical equipment’s like ultrasound machine (about $25,000), Infant Warmer (about $3,995), Miltex Hegar Uterine Dilators (about $40 each), Airflow Manual...
Resuscitator/Ventilator (about $26) and Covidien HET Bipolar Forceps (about $299), etc. accounts for $20 million worth of medical equipment in a warehouse in Portland (Mirza, 2017). Often, healthcare providers are faced with situations where they have to operate under capacity due to the purchase of advanced and expensive medical devices. Applying sharing economy to healthcare sector would facilitate in leveraging technology for ‘access instead of ownership’ and reducing the potential inefficiencies associated with ownership and underutilization. Sharing brings back revenue back to the hospital by lowering overall operating costs.

Comparing with conventional supply and demand models, collaborative models are more resilient, accelerating consumption frequency, minimizing the latent capacity of medical devices, providing a higher return on investment for the healthcare units (hospitals) and improving patient outcomes. Hospitals use any given machine only about 42% of the time, at most, according to a GE healthcare study (Mohamed, 2017). Surgical and medical devices like infusion pumps and ultrasound scanners are traditionally viewed as fixed assets belonging to a specific hospital facility. Consider an example, where one Hospital, say PHU (Primary Healthcare Unit) owns a $250,000 mobile medical asset whose utilization rate is once per week which is quite a small fraction of the time and on the other hand, another Hospital, say SHU (Secondary Healthcare Unit) has also a need of the same medical device. The hyper-consumerism economic model encourages both the hospitals to buy the medical equipment in need at an exorbitant price. Moreover, if SHU comparatively is more financially constrained, then such a model doesn’t make sense at all. So, PHU instead of letting the equipment go underutilized, he can actually generate additional revenue by monetizing the time the medical equipment is not in use. The peer-to-peer or collaborative consumption economic model would actually enable PHU to share it out
to SHU. Thus, creating affordable accessibility of medical equipment to lower end-hospital along with better utilization of equipment’s latent capacity. Cohealo, a start-up in Boston uses this kind of collaborative consumption model instead of the traditional economic model of hyper-consumerism in healthcare. By using sharing economy, the healthcare organization can thus achieve the triple aim, a reduction of 30-40% in healthcare cost (Luisetto, 2016) and rental expenses (Reed, 2018) also support expanding care and an increased revenue capture (Crampton, 2018).

In our model, OEM sells differentiated versions of the same equipment and charge different prices to different hospitals based on the included features. In our proposed methodology, we say that the reduced price of the medical equipment provided by OEM to SHU is associated with reduced features of the medical device. So, if the SHU takes the machine on share from PHU, then it gets a higher quality machine than if it buys directly from the manufacturer. However, given the capacity constraint of the machine and the demand structure of the market of PHU, there is always uncertainty associated with the availability of the device. There isn’t enough literature dealing with such models where the quality of the medical device is being shared under capacity constraints. So, we study under what situations, it is optimal for SHU to actually take the high-quality machine on share from PHU than opting for a non-share strategy, where it buys the low-quality device from the manufacturer and vice-versa. We also study how the market size of both the parties (PHU and SHU), price sensitivity and the quality of the device would affect the equilibrium price as well as the profitability of the healthcare units and also on the socially optimal outcome and consumer welfare. Also, we analyse that whether the existence of such a sharing environment, would lead to cannibalisation of demand for PHU. Thus, we study analytically, how leveraging the underlying notion of shared economy in turning the ‘world of scarcity’ into a
'world of abundance' would facilitate in tapping the excess capacity of the idle machines, reaching to patients without access to quality health care, a decrease in associated operational inefficiencies and higher economic savings (and consumer surpluses) in healthcare along with the scenarios where the sharing environment won’t be beneficial for the parties involved.

**Model and Assumptions**

In our model, PHU is already in possession of the equipment and has bought from OEM at a price \( P \). PHU is a monopolist investor-owned for-profit hospital and SHU is a monopolist not-for-profit hospital run by a private, for-profit firm. Both are profit maximizers. SHU can either buy from OEM at a discounted price or can take it on share from PHU at a rental price. As shown in (Figure 1), PHU acts as the platform owner and is the Stackelberg leader. In the first stage, PHU decides the rental price \( p_r \) to be charged to SHU, if SHU takes on share and the price \( p^B_A \) (Non-share Scenario) or \( p^R_A \) (Share Scenario) for medical services provided to its patients. We have assumed the discount \( d \) provided by OEM to SHU to be pre-decided by the OEM and the capacity of the equipment to be the sum of market sizes of PHU and SHU. In the second stage, SHU decides whether to buy the device with reduced features from OEM or to take the higher quality device on share from PHU and also decide the price \( p^B_K \) (Non-share Scenario) or \( p^R_K \) (Share Scenario) to charge to its patients. We have taken the price of the equipment as a proxy for the quality of the device. The demand equations for the base model are given by equation (1) and equation (2). In the secondary model, we take into consideration of demand cannibalisation for PHU due to the presence of the sharing market.

\[
D_A = \alpha_A - \beta_A p_A + \gamma_A P, \text{ under both the scenario (share and non-share)} \tag{1}
\]
\[ D_K = \begin{cases} 
\alpha_K - \beta_K p_K + \gamma_K (P - d), & \text{if SHU buys from the manufacturer} \\
\alpha_K - \beta_K p_K + \gamma_K P, & \text{if SHU takes on share from PHU} 
\end{cases} \] (2)

Where, \( \alpha_K \) and \( \alpha_A \) represent the market size of SHU and PHU respectively. The impact of the quality of device on demand generation for SHU and PHU are captured by parameters \( \gamma_K \) and \( \gamma_A \) respectively, whereas \( \beta_K \) and \( \beta_A \) captures the price sensitivity of SHU and PHU markets. The optimization models are described in Table 1.

Assuming the game to be a complete information game and the parties to be completely rational, we solve the optimization problems (constrained and unconstrained). Table 2 gives the equilibrium profit and prices.

<td>( \pi^R_A = \left(p_A - c_A - \frac{P}{D_A}\right) (\alpha_A - \beta_A p_A + \gamma_A P) + p_r (\alpha_K - \beta_K p_K + \gamma_K P) ) Such that ( \alpha_K + (\gamma_K + \gamma_A) P \leq \beta_K p_K + \beta_A p_A )</td>
</tr>
</tbody>
</table>
Findings and Contribution

We observe that the profit of SHU under both the scenarios (share and non-share) decreases with increase in price sensitivity of SHU market. Below and above threshold values of price sensitivity of SHU, PHU’s and socially optimal strategy coordinates. Between the two extremes, there exists a conflicting zone. The profit of SHU under non-share scenario decreases with increase in the ratio of PHU to SHU market size. The profit of SHU under sharing scenario increases with increase in the ratio. The switching decision of SHU from “non-sharing” to “sharing” strategy is governed by a particular ratio value. Moreover, using this ratio and the price sensitivity of the SHU market, the strategies of the players can be categorised into coordinating and non-coordinating zones, depending on the interaction between HU’s and socially optimal strategies. The rental price charged by PHU to SHU is more than the price charged by PHU under “no-share” scenario when the quality factor is taken into consideration whereas the relationship reverses otherwise.

<td>$p_e^k = \frac{\alpha_k + \beta_k c_k + \gamma_k (P - d)}{2\beta_k}$</td>
<td>$\pi_k^e = \frac{(\alpha_k - \beta_k c_k + \gamma_k P)^2}{4\beta_k} - (P - d)$</td>
</tr>
<tr>
<td>SHU</td>
<td>Share</td>
<td>$p_a^e = \frac{\alpha_a + \beta_a c_a + \gamma_a P}{2\beta_a}$</td>
<td>$\pi_a^e = \frac{[\beta_a(\alpha_k - \beta_k c_k + \gamma_k P) + \beta_k(\alpha_a + \beta_a c_a - \gamma_a P)]^2}{4\beta_a(2\beta_a + \beta_k)} - P$</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$p_e^k = \frac{\beta_k(\alpha_k + \beta_k c_k + \gamma_k P)}{2\beta_k(2\beta_a + \beta_k)}$</td>
<td>$\pi_k^e = \frac{[\beta_a(\alpha_k - \beta_k c_k + \gamma_k P) + \beta_k(\alpha_a + \beta_a c_a - \gamma_a P)]}{4\beta_k(2\beta_a + \beta_k)^2}$</td>
</tr>
</tbody>
</table>
Proposition 1: For $A < \gamma K < B$, where $A$ and $B$ are functions of $\alpha_K, \alpha_A, \beta_K, \beta_A, c_K, c_A$ and $P$, then we have $p_A^R > p_r > p_A^B > p_K^B > p_K^R$.

Proposition 2: There exists a threshold for discount $d_c$, such that for $d < d_c$, SHU opts for sharing however for $d > d_c$, SHU opts for buying the device from the manufacturer directly.

Proposition 3: When SHU is indifferent between buying the device and taking it on share, then the socially optimal outcome is to share the higher quality device rather than buying the inferior one, whereas when the socially optimal outcome is indifferent between sharing or buying, then SHU opts for buying the inferior medical device.

Limitations

The results are obtained using deterministic demand of the hospitals. Our model does not incorporate any kind of uncertainty of parameters. We assumed that both the parties have complete information about each other’s cost structure, which is not always true. In fact, parties have partial information, specifically about the cost structure of the other party involved. In such a case, the cost can be assumed to follow a certain distribution.

Abstract

Original Equipment Manufacturers (OEMs) in the German Medical Technology (MT) sector are facing a strong competition from low-wage countries developing, manufacturing, and distributing high-quality products globally. For this reason, organisations in this sector require orientation in the implementation of SCM policies to reduce operating cost and to create value for their customers. A multiple case study was conducted to identify SCM issues and best practices in this sector. This study contributes to healthcare operations management literature with a tailor-made assessment tool. Its findings offer new priorities for managers, particularly if they are contemplating a re-engineering of their SCM strategies.

Keywords: Supply chain network design and analysis, Collaboration and coordination issues in SCM, Medical technology industry

Introduction

Medical technology is an innovative, fast-growing and promising industry, particularly so in Germany as it is the third largest market in the world behind the US and China (BVMed, 2018). Around 1,200 small and medium-sized enterprises (SMEs) represent the core of this sector (BMBF, 2017). In 2017, the sales volume of MT organisations rose to 29.9 billion euros, with an export rate of 64% (BVMed, 2018).

Despite this remarkable growth, the Medical Technology industry in Germany is faced with a number of challenges. Reportedly, Germany’s statutory health insurance fund (gesetzliche Krankenversicherung) has experienced funding difficulties, forcing administrators to reduce fees and thus expenditures on Medical Technology (Hartford, 2014; Focus, 2016). Furthermore, manufacturers rely strongly on new product development to sustain or increase their market share, and with products having lifecycles not longer than 3 years, short development times and regulatory approvals become critical issues (Hempel, 2017; BVMed, 2018). Additionally, Chinese and Indian companies are also lined up to be frontrunners in terms of cost, workforce, and market capture, pressuring German manufacturers to produce and distribute cost-
efficient devices (Marucheck et al, 2011; Hempel, 2017). In this environment, the search for rationalisation potential becomes critical. Studies (J & M, 2010) show that a defined supply chain strategy often falls short in this sector. Major deficiencies reported are the absence of a formulated strategy, the lack of efficient planning and coordination processes, along with unreliable sales forecasts.

In this paper, the authors investigate multiple cases of OEMs involved in Medical Technology Supply Chains (MTSCs) in Germany and use the results of the analysis to identify both areas at which these organisations excel as well as areas of improvement which require addressing during the design and operation of their SCM strategies. This paper builds on previous research conducted by the authors (Garcia-Villarreal et al, 2019) and is organised as follows: first, a review of the literature is reported. Then, the research aim and focus are formulated, followed by the justification of the selected methodology and case study design. Next, the findings are presented and analysed. Finally, this paper concludes by stating the implications for theory and management practice along with research limitations and avenues for further research.

**Literature review**

*Healthcare & Medical Technology Supply Chains*

Supply chain management as an area in operations management literature is extremely well served whereas there is a real dearth regarding its focus on medical technology supply chains and their agility as exemplified by recent literature (Gligor, 2014; Mandal, 2017). Mentzer et al (2001, p. 4) define supply chains as a “set of three or more entities directly involved in the upstream and downstream flow of products, services, finances, and information from a source to the customer”. There are three major players in the Medical Technology supply chain: producers (product manufacturers), purchasers (group purchasing organisations, or GPOs, and wholesalers/distributors), and healthcare providers (hospital systems and integrated delivery networks, or IDNs) (Burns et al, 2002).

The manufacturers (producers) in the supply chain can be broadly classified into three groups namely, pharmaceutical, medical-surgical, and device manufacturers, the latter being the object of this study. Their products are then purchased by GPOs, wholesalers, distributors and in some cases independent contractors, and then delivered to providers like hospitals, integrated delivery networks (IDNs), physicians (individual clinics) and pharmacies. Customers (payers) in this supply chain are local governments, employers, and individuals. They pay the providers through fiscal intermediaries like insurers, health maintenance organisations (HMOs) and pharmacy-benefit managers. Smith et al (2012) provides a detailed view of the medical devices supply chain, in which the main product flows between the key players are clearly represented (see Figure 1), underlining the heavy influence of intermediaries or third-party players.

Studies by Burns (2000), Dacosta-Claro (2002), J and M Research (2010), and Mayer (2013) indicate that a significant portion of the costs associated with supply chains in the health care sector can be reduced by adopting strategies already deployed by the industry sector (e.g. automotive). For this reason, identifying areas of opportunity and areas managed successfully by these organisations becomes very important.
Review of SCM assessment tools available in academic literature

The literature review identified a number of tools available for assessing the performance of logistics and manufacturing companies within their supply chains, which are briefly presented and discussed in this section.

Tummala et al. (2006) conducted a survey research with top and middle managers within a large enterprise as respondents in order to examine operational issues concerning success factors that are necessary when implementing SCM plans in one large manufacturing firm. Dimensions for evaluation were 'customer-supplier relationship', 'information and communication technology (ICT)', 're-engineering material flow', 'creating corporate culture', and 'performance measurement'. Their study revealed that resource allocation could be enhanced in areas such as information systems, goal-setting, training personnel, and aligning SCM initiatives with current priorities and committed resources in that particular organisation. Although this assessment tool did focus on many factors related to logistics and SCM, neither 'make' (e.g. manufacturing issues) nor 'return' processes (e.g. reverse logistics, green supply chain) were considered in it.

Gunasekaran and Ngai (2003) conducted an interview-based case study on a small third-party logistics (3PL) company in Hong Kong that had been successful in its overall business performance and in satisfying its customers. In this study, they designed a framework for developing an efficient 3PL system. While their assessment tool appeared easy to use, it only included five major dimensions for evaluation ('strategic planning', 'inventory management'; transportation planning'; capacity planning'; and 'information technology'). It can be noted that this assessment tool was not intended for manufacturing firms, but rather for 3PL companies, as neither of the dimensions considered any form of evaluation criteria aimed at identifying issues in the development, production, and quality assurance of items ('make' processes).

Finally, Thakkar et al. (2011) used a case study approach to identify issues in SMEs of Indian origin. The assessment tool developed for this study offered a thorough approach, consisting of the evaluation of Critical Success Factors (CSFs) 'effective partnership', 'improve communication', 'logistics integration', 'supply chain business strategy', 'buyer-supplier relationship', 'effective planning and control', 'trust among supply chain partners', and 'availability of performance management tools'. However, the dimensions under review appear to be too much leaned against the 'source' side of the business.
Research methodology

The research objective of this study is to explore key areas of improvement of German MT OEMs during the design and operation of their supply chain strategies. Therefore, this study was driven by the following research question:

- What are the strengths and weaknesses of German MT OEMs in regard to their supply chain strategies?

In order to answer this question, an exploratory research with a multiple case study approach was selected for three reasons: (1) the literature review revealed limited insights concerning weaknesses and strengths in SCM practices in the MT sector. In such an embryonic research field, a qualitative research provides better means to identify patterns and develop theory (Edmondson and McManus, 2007). (2) As the researchers were able to interact with respondents, perspectives were better understood (Boyer and Swink, 2008). (3) Case studies encourage management involvement, which helped this research to generate managerially relevant knowledge. Established methodological guidelines for case study research were observed (Eisenhardt, 1989; Robson, 2011; Yin, 2009). Fourteen in-depth case studies of manufacturing organisations were conducted to obtain a greater understanding of the main issues of German MTSCs (see Table 1). In order to enrich the results, the selected case study organisations were of different subsectors (e.g. laboratory equipment manufacturing, electromechanical MT, non-active implantable technology, etc.) and sizes, with eight Large Enterprises (LEs) and six SMEs participating.

A suitable assessment tool was required for this study. The literature review identified and discussed available assessment tools, which were deemed too simplistic, too complex for practitioners to use regularly, missing processes featured in the SCOR-Model (Supply Chain Council, 2008), or not suited for the context of this study. For these reasons, an assessment tool was designed, piloted, and implemented to identify strengths and weaknesses of SCM strategies in the case organisations (see Figure 2). The theoretical foundations of this tool as well as the dimensions under review are based on identified CSFs by the authors in previous research (Garcia-Villarreal et al, 2019).

![Diagram of assessment tool]

**Figure 2. Example of mapping results of Case Organisation L using the assessment tool for this study**

**Research findings**
This study identified areas where case organisations excelled at their SCM strategies as well as areas requiring immediate attention by SCM practitioners. These are reported here.

**Strengths in SCM practices of MT organisations**
Strengths of MT organisations (predominantly LEs) were found in four areas: (1) the design of OEMs’ supply chain capabilities according to their customer value propositions; (2) the deployment of intelligent product design; (3) the use of ‘track and trace’ systems to increase supply chain visibility; (4) an expansion of the role of OEMs to deliver more value for their customers.

In terms of the design of the supply chain capabilities according to their customer value propositions, this study identified three fundamental approaches: a flow-oriented approach, a batch-oriented approach, or a combination of both. The flow-oriented supply chain is set up on the basic condition of a quite fixed series of repetitive transactions (material, information, payments). Case Organisations A, E, L, and N had a flow-oriented approach to their supply chains. What these companies had in common is the production of mass articles with a low degree of variation and in high volumes.
These companies strived to reduce costs in their supply chains by improving their standard, repetitive operations. Conversely, Case Organisations D, M, and I had adopted a batch-oriented supply chain strategy for their operations. These companies had three things in common: they produced niche products according to customer specifications, they did not manufacture these products in high volumes, and they sold these items at a high price. The supply chain required to carry these products needed several arrangements: Manufacturers had to interact with a larger number of raw material suppliers; each contract with hospitals or clinics needed to be individually priced and logistics details had to be arranged individually; instead of a continuing number of shipments, there was a limited number of batch deliveries.

The basis for the economic success of German MT is the broad range of innovative products it creates, with about a third of its revenues generated from products that are less than three years old (BMBF, 2015). For this reason, the product development process becomes crucial for the supply of innovative products to their customers (Medina et al. 2013). Case organisations in the study reported a transition from an inwardly-oriented approach to product design (first developing a product then searching for a market) to a more customer-oriented approach (understanding customer needs and developing products thereafter). Involving surgeons in the innovation process proved beneficial to OEMs, as development, product test, and regulatory approval times could be reduced (Lettl, 2013), while increasing product variety to address users’ specific needs (Al-Zu’bi & Tsinopoulos, 2012). Given the importance of the role of users in the design of products, Case Organisation D cooperates actively with surgeons in the design of medical devices and names their finished products after the physician that inspired or co-designed them. Activities in product development process have an influence on the performance of other organisational functions, such as procurement, manufacturing, marketing and sales, and service. Case Organisation A launched a project to standardise information flows between sales, product development, and procurement in order to reduce the risk of dependency to niche suppliers. These efforts enhanced their material availability while reducing the risk of material obsolescence. Case Organisation J analysed their product portfolio in an effort to standardise their raw materials and their part numbers, with the effect of decreasing their supplier base and streamlining their purchasing, order picking, and assembly processes. Case Organisation D focused on reducing manufacturing costs (technology, methods, and materials) through a re-examination of their product portfolio. Finally Case Organisation H launched a project to improve their product update services in order to cut manufacturing, procurement, inventory, and after-sales costs.

Several organisations in this study have made supply chain visibility a top priority in their agendas and have made significant investments in this area. One major reason is to fight product counterfeits. Another reason is that their customers require status reports about shipments in real time: hospitals are increasingly under pressure to schedule both patients and surgeries more efficiently, both for humanitarian and economic reasons, as costly hospital equipment (e.g. computer tomographs) cannot afford downtimes. Therefore, the recipients are requiring effective “track and trace” instruments to monitor the shipping status in real-time. Clinics expect real-time information, especially for unplanned maintenance work. At Case Organisation K, 30 to 50 per cent of the maintenance services are unplanned. Case Organisation K needs to supply 98 per cent of all spare part orders within 24 hours – and, if possible, in all 132 countries covered by the manufacturer. This poses a challenge for freight forwarders: if the shipment is half an hour too late, it is already considered late. Therefore, Case Organisation K has been working with third party logistic providers to digitalise their distribution chain. In
order to enhance their response rate, Case Organisation K defined milestones with the freight forwarders along the supply chain. Once a milestone had been reached during the transportation of products, it was the freight forwarder’s responsibility to deliver a push message to both manufacturers and recipients.

One of the largest cost items for hospitals and clinics, as reported by some case organisations, is the management of products such as endoprosthetics, pacemakers or surgical covers. Some case organisations are reportedly working to improve hospitals’ operational procedures in the sterilisation departments, in operating rooms, as well as in the hospitals’ internal logistics. Effects of these projects are shorter throughput times for the supply of instrument trays to operating rooms, reduced stocks of instrument trays in storage rooms, and streamlined logistics processes for hospitals. Additionally, Case Organisation K reported working on taking over the repair management functions of hospitals in order to consolidate internal cost and reduce the replacement rates of instruments. In the same context, Case Organisations D and K have been working on expanding their capacities for the repair of used instruments, in order to reduce the hospitals’ replacement rates. For this reason, it is expected that OEMs can gain a competitive advantage by working together with their customers to streamline their internal processes and to reduce managerial efforts.

Weaknesses in SCM practices of MT organisations
In terms of the main SCM issues in this sector, this study identified four areas where the severity of SCM issues is critical: (1) a lack of rigour in the deployment of sales and operations planning; (2) poor first-tier integration; (3) distribution networks not set up according to customer needs of product availability; and (4) a strong emphasis on quick wins and quarterly savings hindering change at management level.

Regardless of their products and services or their size, 11 (C, E, F, G, O, A, I, L, J, M, N) of the 15 case organisations in the study have experienced some form of disruption in their respective supply chains that has hindered their ability to harmonise customer demand with production and distribution capacities. Reasons for these disruptions are, among others, a low level of trust, integration, and information sharing between OEMs and both customers and suppliers; and a lack of rigour in the deployment of their existing Sales and Operations Planning (S&OP) process, fostered by conflicting target and performance appraisal systems within the organisations and developing counter-productive behaviours such as silo-thinking within organisational departments. This issue has particularly affected SMEs, which, in the absence of joint planning with customers, has made the position of their supply chains vulnerable.

Several organisations reported having issues related to their current procurement strategies and approaches. Similar patterns were identified for both LEs and SMEs: LEs reported on having adopted select procurement strategies (Kanban, Vendor-Managed Inventory (VMI), Electronic Data Interchange (EDI), Just in Time (JIT)) and have come to expect their supplier base to become JIT suppliers, but in the absence of cross-functional integration within the OEMs, the implementation of these strategies appeared to be disjointed and did not lead to a full utilisation of their systems’ capabilities. In addition, approaches to procurement of Case Organisations E, G, and O seemed to be one-sided, apparently seeking no win-win situations with suppliers and thus hindering collaboration. In contrast, issues shared by SMEs range from underprivileged power relationships with suppliers (cases M and L), inaccurate master data hindering an efficient information exchange with suppliers (cases J, A, N), and raw material shortages due to fluctuating prices and an almost exclusive focus on local sourcing (cases I, L, M). Evidence of this disconnect in the relationship with suppliers could be
found in the presence of the high raw material inventories and slow turnover ratios for almost all cases referenced above.

Additionally, Cases B, G, O, A, L, I, J, and I shared that their distribution network was not set up according to customer needs of product availability. Therefore, these companies were forced to ship their products via express delivery at high cost. In the case of Case Organisations I, L, and N, this is partly explained due to the fact that reportedly, the design of efficient logistics structures had not been focus of much work, as before the crisis in 2009, there had not been a need to change. Now these companies are catching up with several concepts well established in the automotive industry. For instance, Case Organisations L, J, M, and N—all SMEs—, are currently embarking on projects of their own seeking to integrate external logistics service providers. They believe that outsourcing distribution will help them focus on their core competencies, access new markets, optimise transport routes, and save them the time and money they would have invested in setting up their own distribution facilities.

Finally, it appeared that several managers have merely added the term ‘supply chain’ to their jargon without adopting a SCM mind-set. A strong emphasis on quick wins seemed to limit the ability of several case organisations to establish appropriate processes and relationships or to anchor them in the organisational culture. For instance, Case Organisations G and O seemed to have organised all their SCM activities around their logistics and customer service activities, yet these efforts were focused primarily on direct ‘A’ customers and were reactive in nature, neglecting ‘B’ customers with the potential to transform into ‘A’ customers. While all respondents believed that SCM could assist their respective companies to succeed in their marketplace, they did recognise the difficulty to bridge organisational boundaries in their relationship with suppliers. In this sense, the procurement strategies of several case organisations (e.g. Cases E, O, G) appeared to be one-sided, seeking no win-win situation, thus hindering collaboration.

Furthermore, several case organisations seemed willing to invest in technological solutions to solve operational challenges. Respondents I, M, and L made a case for investments on better information technologies hoping that this would provide their supply chains with substantial improvements in terms of efficiency, collaboration, and responsiveness. While this may be partially true, some respondents warned that improving collaboration between stakeholders required more than an enhanced information platform. Therefore, they had been working with core first-tier suppliers and customers to (1) define the boundaries and strength of their relationships; (2) establish communication requirements; and (3) select appropriate technologies based on an analysis of these requirements.

Only a few companies have established a SCM culture that promotes fact-based decision-making. For instance, case organisations such as C and D had been installing common goals in SCM for all departmental functions within their organisation. Furthermore, these organisations have understood that cultures change slowly and that changing long-standing ways of doing things require appropriate strategies and serious commitment from management. Therefore, they have been involving owners, senior managers, and middle management in transformation projects, as they understood that a real change could only occur with direct involvement of stakeholders.

In this context, the middle management seemed to have a key role both as an intermediary between the goals of senior management and the priorities of the operational staff, and as an agent for sustainable changes in operational policies. For these companies, SCM was not seen a project but as a long-term journey.
Conclusion
The objective of this study was to identify strengths and weaknesses of current SCM practices of OEMs in the German MTSC sector. The interactions with fourteen OEMs have helped to identify both areas where these organisations excel and areas where the severity of the issues requires immediate attention.

Areas where MT organisations excel are (1) the design of OEMs’ supply chain capabilities according to their customer value propositions; (2) the deployment of intelligent product design to reduce sourcing costs and to build stronger partnerships with physicians; (3) the enhancement of supply chain visibility with “track and trace” systems; and (4) designing and implementing individual concepts for supply and management of medical devices for hospitals and clinics.

On the other hand, major issues identified in this sector include: (1) a lack of rigour in the deployment of sales and operations planning; (2) poor first-tier and second-tier integration; (3) misaligned distribution networks; and (4) a strong emphasis on quick wins and quarterly savings hindering change at management level.

This research contributes to knowledge in the form of an assessment tool that identified strengths and weaknesses of SCM strategies in the MT sector. Although a number of tools available for assessing the performance of organisations within their supply chains were identified, these appeared to be either too simplistic, too complex for practitioners, lacking important dimensions for evaluation, or not suited for this research context. In an effort to fill this gap, this study developed its own tool, providing an approach to evaluation that considers the five basic business processes required to satisfy customer demand (‘Plan’, ‘Source’, ‘Make’, ‘Deliver’, ‘Return’) (Supply Chain Council, 2008).

Researchers can use it as a means to conduct further research work in other contexts. Additionally, managers of MT OEMs who wish to develop or restructure their organisations’ SCM policies can benefit from this tool, as it provides them with an orientation for resource allocation. The main limitation is that this tool is tailor-made for organisations in the MT sector. Although this is a limitation, it does however give evidence to how closely this tool is designed for the sector in focus, as it considered this industry’s characteristics. Further research work can use this assessment tool to test its applicability in other contexts other than the German MT sector.

Abstract

A digital patient portal is a promising mechanism to support greater patient engagement. Yet questions remain about how adoption of these portals can be encouraged since patients and providers still face a lot of resistance. This paper examines, by building on the MOA framework, if and how usage behavior is influenced. With action research in an innovation project at Ghent University Hospital we collected data (interviews, observations, log data, questionnaires) of involved parties. Preliminary results showed higher use of the portal by implementing changes. The role of intrinsic and extrinsic motivation of all included parties needs to be further investigated.

Keywords: action research; eHealth; motivation, opportunity and ability framework (MOA); patient portal.

Introduction

In the last decades, day surgery has steadily and significantly grown in countries with established stable economies (Jarret et al., 2006). Advances in surgery and analgesia, changes in clinical practice and in the attitude of the surgical team, as well as the establishment of dedicated day-surgery facilities with dedicated staff and well-defined care pathways, together with financial incentives have made this development possible (Leroy et al., 2017). Ambulatory surgery becomes more important and will be further promoted by the government; it is safe and cost-efficient but quality must be guaranteed. As more complex operative procedures will be performed on a day care basis, patient follow-up has to be intensified. This increase in day surgery entails some challenges,
mainly in the continuity of care and in patient follow-up after day surgery unit discharge. Persisting postoperative pain, post-discharge nausea and vomiting, and wound problems remain critical symptoms that necessitate continuous monitoring (Apfel et al., 2012; Goldfarb et al., 2017; Odom-Forren, 2013). Systematic e-assessment can increase patients’ quality of recovery and identify key areas for improvement in peri-en postoperative care. As such, an eHealth solution could be the answer to some of these challenges.

The implementation of technology in the health sector, popularly known as eHealth, is emerging as one of the most rapidly growing areas in healthcare today (Srivastava et al., 2015), with the potential to provide innovative solutions to health problems. The emergence of the Internet and the electronic health record has brought new opportunities for patients to play a more active role in his/her care. The implementation of a digital patient platform could provide in the requirements that an ambulatory surgery center needs (Ammenwerth et al., 2012).

An active integration of the patient in his/her treatment bears multiple potential benefits. Certainly as we notice a change in the patient’s role from a patronized patient to an informed patient, and further to a responsible, autonomous and competent partner in his or her own care (Bravo et al., 2015). A patient portal is an online platform that provides patients with access to their health record, improves the patient-provider communication, and enables patients to take control of their condition(s) (Otte-Trojel et al., 2015). So a patient portal is a promising mechanism to support greater patient engagement. However, the expected benefits of the implementation of such an eHealth technology under the form of a digital patient platform are not always a match with the actual outcomes (Van Gemert-Pijnen, et al., 2011).

EHealth technology must be developed as a user-friendly digital tool with benefits for the different users. Therefore different stakeholders have to work together to develop and implement the application in everyday practice. Although new technologies can offer the new opportunities and benefits, stakeholders don’t always seem to appreciate it (Hee-Woong & Kankanhalli, 2009). There is often a mismatch between the expected benefits eHealth technology can offer to the users and the actual outcomes in practice (Van Gemert-Pijnen, et al., 2011). In addition, healthcare professionals often have a sceptical view on the digital transformation and do not see the potential benefits for themselves and their patients. Van Gemert-Pijnen et al. (2011) demonstrated possible explanations of this mismatch: (1) the absence of a pre-defined scope and clear objectives that cover the requirements of all stakeholders; (2) the lack of coordination and communication between the relevant stakeholders; (3) the position of the user and the level of their involvement during implementation. If users do not see the benefits in using technology, they will resist using it as it looks to be time consuming and frustrating. Above that, there are situations where the innovation of eHealth technologies is not enough reimbursed because of a lack of financial trust by investors. Further, it could also be that the implementation of eHealth is not supported by legislation, which slows down the development process (Gemert-Pijpen et al., 2011).

In an effort to understand usage or non-usage of technology, researchers have frequently turned to technology acceptance models. The Technology Acceptance Model (TAM and TAM2) (Davis, 1989) and the Unified Theory of Acceptance and Use of Technology (UTAUT) (Venkatesh et al., 2003) are the dominant approaches in the technology acceptance research. The models suggests that when users are presented with a new technology, a number of factors influence their decision about how and when they will use it (i.e. ‘perceived usefulness’ and ‘perceived ease of use’). These models
however, are not always fulfilling (Peek et al., 2016) and further research is needed. Agarwal et al. (2010) stress out the importance of further research in the field of Health IT as following: “The healthcare industry faces the same challenges as other industries while integrating IT. At the same time, however, the healthcare industry has its unique features and attributes.” Questions remain about how adoption of patient portals can be encouraged since patients and providers still face a lot of resistance (Irizarry, 2015). We investigate the actual use of a patient portal peri-operatively in ambulatory surgery and how this is perceived by patients and healthcare workers. Secondary we try to identify and remediate reasons for non-use.

**Framework**

*Motivation–opportunity–ability (MOA) framework*

The integrative motivation–opportunity–ability (MOA) model proposed by Ölander and Thøgersen (1995) was constructed to explain customer actions. The MOA framework uses information on the targeted stakeholders’ motivation, opportunity and ability to undertake the preferred behaviour (Rothschild, 1999). A deeper understanding of these three key aspects would allow programme developers to formulate effective behavioural change strategies. In this model, “Motivation” influences “Behaviour” with “Ability” and “Opportunity” as moderating influencing factors (Figure 1).

Some theoretical models used in information system research may lack explanatory power and consistency because of their failure to provide an adequate means of accounting for contextual and situational factors which influence behaviour. The motivation-opportunity-ability (MOA) framework addresses these problems for important new areas of information system research by theorizing two of the most critical factors, ability and opportunity, on the link between motivation and behaviour. The MOA framework has been used in many studies in different areas of research. For example, MOA was used to discuss the public health and social issue behaviours (Rotschild et al., 1999) and consumer behaviour (Ölander & Thøgersen, 1995).

![Figure 1 – Ability, Motivation, and Opportunity Theory (Hughes, 2007)](image)

Building on the MOA framework “Motivation”, “Opportunity” and Ability”, are defined as patients’ motivation, opportunity and ability to adopt the digital patient portal. MOA theory is used as a foundation because it is believed that in the context of patient portal adoption “Motivation” is considered as the drives, urges, wishes or desires which initiate the patient’s intention to use the patient portal. “Ability” can facilitate patients in adopting the patient portal and “Opportunity” is interpreted as situational factors that encourage patient in the adoption of digital patient platform. “Behaviour” reflects the “adoption” of the digital patient portal.
Methods
This study presents preliminary data of the innovation project in Ghent University Hospital, Ghent. The ambulatory surgery unit at Ghent University hospital aims at electronic communication with both patient and caregivers involved in ambulatory care (e.g., in-hospital, out of hospital, general practitioner, physiotherapist, home nursing). In cooperation with CoZo (Collaboratief Zorgplatform), an electronic hub which allows safe and efficient multidisciplinary communication, a digital patient platform was developed.

Design
To conduct the study we opted for action research. Action research involves actively participating in a change situation, often via an existing organization, whilst simultaneously conducting research (Cordeiro & Soares, 2018). Researchers who believe that existing practise or issue can be improved or refined can attempt to develop and implement new approaches through action research (Kaplan et al., 1988). As such, we had to develop a coherent process, posit a theoretical framework and align these with the research aims and procedures, and local transformation needs. As stated by Denscombe (2010, p. 6) our action research strategy's purpose is to solve a particular problem and to produce guidelines for effective practices. In this case best practise could increase the adoption of a digital patient portal.

Setting
We included two care pathways to measure the adoption of the digital patient platform. Patients planned for knee arthroscopy or sinus surgery.

The patient platform includes (1) an informative part: visualization of the individualized care path (different steps can be chosen for each patient which makes the pathway customized), provision of reliable information about the diagnosis and the treatment, links to relevant websites, contact details of the treatment team, and (2) an active part with the possibility to have secure conversations with the treatment team, self-registration of complaints and other problems in diaries and other questionnaires, and a question prompt list (Figure 2).

Data collection
We conduct a longitudinal study with different phases. In each phase we implemented, according to the action research strategy, new insights learned from the former phase. A pilot study started in September 2017 introducing the digital patient platform to the participating care processes and the stakeholders. The first phase of the study started in August 2018 and was recently finalized. Meanwhile, a second phase is initiated (see further). In each phase data is collected, analyzed and conclusions are taking into account to be able to evolve to the next phase.

A multimethod approach, combining qualitative and quantitative data, was chosen because of the nature of the research. Collection of both qualitative and quantitative data bolsters the findings by combining the strengths of each method. Data was collected through interviews (with patients, involved caregivers and physicians), observations (first introduction to patient with platform, team meetings), log data collected from the patient platform, clinical outcome measures and a patient questionnaire (see Table 1).
Semi-structured interviews were held with patients and involved care providers to gain deeper insight into the user-friendliness and applicability of the portal. We explicitly included patient who did not use the patient portal as well to understand why the portal was not used and what factors could trigger patients to use the portal.

Additionally, patients received a validated survey. This survey, based on the questionnaire of Bakken et al., 2006, assessed the user-friendliness and satisfaction with the patient portal. The original scales were translated in Dutch using the standard back-translation technique. A fourteen-item scale for user-friendliness was used. We used eight items for the satisfaction scale. The usability of the eight different sections of the system was also asked (see Figure 2). Responses were provided on a five-point Likert scale, with anchors ranging from 1 (strongly disagree) to 5 (strongly agree), and for usability from 1 (not at all useful) to 5 (very useful). Previous research provides evidence of high reliability and validity evidence regarding perceptions on eHealth (Demiris, Speedie, & Finkelstein, 2000).

Similarly, system-related log data were tracked; namely the number of logins on the system (patient and caregiver), the number of times the various sections were consulted, number of messages sent and number of completed diaries and questionnaires. Demographic, tech savviness, satisfaction and clinical variables were also collected from patients (users and not-users). To compare the baseline need of the patient in information support we calculated the profile of the patient at the start of the study. This data will be used to compare groups with different needs.
Sample
All patients from the selected care pathways willing to participate were included, this results in a convenience sample. As we noticed in the pilot study that only few patients willing to use the patient platform actually used the platform (17%), we opted not to randomize to have sufficient data in this project. Also, we described the reasons why patients did not participated in the study.
Patients with one of the following criteria (1) not having a computer with an internet connection, (2) not having the Belgian identity, (3) not Dutch speaking, (4) having a cognitive and/ or psychological disorder (as assessed by the research team) and (5) unable to read or write (as judged by the research team) were excluded. All involved caregivers were included. The flow of the use of the patient portal can be found in Figure 3.

Figure 3 – The flow of use of the Digital Patient Platform

Data analysis
Interviews were conducted both by telephone and face to face with the end users (patients and caregivers) and were recorded on tape. Immediately after the interview, the findings were noted. The interviews were transcribed verbatim. The qualitative data were analyzed through thematic content analysis. The analysis was carried out by two researchers, both experienced in qualitative research.
The sample and study variables of the patients will undergo descriptive statistical analysis. Cronbach alpha reliability scores will be calculated to test the internal consistency of the scales. Variance analysis (Anova) will be used to compare groups.
Ethical considerations

The study protocol was approved by the institutional review board and all participants took part voluntarily. Written informed consent was obtained from all patients.

Results

In phase 0, 252 patients were willing to participate. However, a substantial number of patients were not enrolled (n=51). Main reasons for not enrolling where: not having the Belgian nationality (n=13) or not speaking Dutch (the language used in the portal, n=8); not having an eID reader, PC and/or smartphone (n=24), or patient not feeling digital competent, lack of interest or lack of added value (n=6). The healthcare professionals acknowledged that the technological barrier under the form of the need to use the eID
user (according to the European GDPR guidelines), has a negative influence on the user acceptance.

Some patients were not asked or informed to enroll (exact data incomplete) due to organizational issues (e.g., forgot to ask patient, too busy) indicating a need to automate this process. Within the orthopedic setting this was caused by a turnover in personnel, where at the otorhinolaryngology setting this was rather due to lack of motivation of the nursing staff. In short, in the pilot study we were confronted with a high number of not included patients and low use of the portal by patients who agreed to participate.

Preliminary data of phase 1 (work in progress) included 85 patients (who underwent surgery before April 2018) that enrolled in the study. Fifty one patients did not enroll in the study, this for the same reasons as in phase 0, but notable more number of patients being not interested (n=29). Forty one % of the patients were not asked or not informed. Observations and interviews showed that the nurses allocated to enroll the patients had a major influence on the latter two reasons of non-participating. High work pressure, shortage of staff and lack of interest in the project (from the otorhinolaryngology setting) resulted in low enthusiasm. As such, less effort was made to include patients.

Forty five % (n=38) of the enrolled patients used the patient platform. This suggest that there is interest but patients do not perceive an urge to log in. The majority of the actions taken on the platform where gathering information (n= 1214); while 71% of the patients actively used the platform to register questionnaires or diaries (n= 27). Rarely a conversation with a care provider was started (n=15) and the prompt list was not used. A positive trend of higher use of the patient portal by patients was found in time. This being the results of different measures taken by the innovation team (e.g., prompts to patients by mail, better inform and motivate involved care providers) during the study (see Table 1).

Interviews demonstrated that patients using the portal find the portal a user-friendly tool, mainly for searching new information. Our observations showed that patients who are strongly motivated by the nurse to use the portal (e.g. by explaining the added value of the patient portal) leads to higher use. But we also observed a high lack of involvement of the surgeons who did not inform their patients about the patient portal. Data analysis of the interviews with non-active patients might reveal important insights why they did not use the portal. This will be supplemented with the data from the questionnaires. Also comparisons between the two cases is lacking at this moment in the data analysis.

As previously mentioned, patients have the possibility to use the functionalities of the digital patient platform both on computer and smartphone application. One third (n=13) used the smartphone app.

The profiles of users versus non-users will be compared after analysis of the questionnaires. Next step is to focus on motivating and lowering the threshold by guiding the patient in the first electronic identification in the portal during face-to-face contact preoperatively during preoperative anesthetic consultation (nurse or anesthetist). Additionally, interviews demonstrated that patients do not always see the added value of the portal. Therefore, a patient portal for day surgery involving a more complicated care
process (e.g. in pain experience) will be tested to investigate whether there is a higher perceived usefulness compared to the already included care processes in phase 2.

Discussion

Our study supports Classic Technology Acceptance theories by demonstrating the importance of ‘perceived usefulness’ and ‘perceived ease of use’ of technology towards the intention to use this technology (i.e., the patient portal). However, we also showed the importance of improving the operational process and applying operational features (such as automatically linking patients to the portal for standardized care processes).

Our findings support the MOA theory. The patient needs the ‘ability’ to use the patient portal. Patients not equipped with the right (access) resources cannot use the patient portal, substantiated by the high number of patients that do not have access to the portal due to technical issues (e.g. no eID, no Belgian identity). Developers should beware of this group that cannot be reached and should not neglect them as they are probably more vulnerable. Another important factor is that the patients must identify the ‘opportunity’, patients not sensing the usefulness of the portal do not have an urge to use the portal, and thus not find it an opportunity. As such, we must not believe that all care processes are effectual for the use of a patient portal. Patients must see an added value for themselves (intrinsic motivation) when using the patient portal in their care process. Taking into account the opinion of the patients is of major importance in selecting the right care processes. But above all, to achieve patient engagement we highlight how third parties (in this study the physician or nurse who has a direct relation with the patient) are an important asset to extrinsically motivate patients to use the portal. Provider endorsement is one of the most influential factors of impacting patients’ adoption (Ross et al., 2016). The theoretical framework will guide us in making the difference in intrinsic and extrinsic motivation of the patient and how these can be empowered resulting in higher use of the portal. Further analysis will provide more insight in why the portal is not used.

Conclusion

The introduction of eHealth has the potential to provide innovative solutions to health problems. However, eHealth technology should be developed so users can’t find any reason not to use it. Patients who use the portal are positive and we notice an increase in the use and registration of questionnaires and diaries at the portal. This illustrates that by action research we can implement changes that improve eHealth implementation (i.e. the use of the digital patient portal). However, the development and understanding of the MOA constructs, particularly the important role of intrinsic and extrinsic motivation, might provide the potential to attain a higher use of the portal.

Abstract

There is a demand from within the professional healthcare organizations that operational and organizational changes must be evidence-based. “Process theory – The principles of operations management” is the closest to evidence-based practice that our research field has come up with to date. The purpose of this article is to operationalize the theory by proposing a design procedure based on it and to test that procedure on the problem of increasing the capacity of a surgery unit at a large hospital. The present state analysis part of the procedure was carried out and has led to new insights for the hospital’s management.

Keywords: case study, healthcare, process mapping

Introduction

Hospitals, all around the world, need to increase productivity, in order to meet the increasing demand of an ageing population without increasing the costs. Many hospitals in Sweden have lack of capacity to meet the present demand and there are long queues of patients waiting for access for specialised care (Stiernstedt, 2016).

Sahlgrenska University Hospital is one of the largest hospitals in Sweden and provides emergency and basic care for the inhabitants of the Gothenburg region and highly specialised care for West Sweden and, with about 700.000 and 1,7 million inhabitants respectively (Sahlgrenska University Hospital, 2019). It is also Sweden’s centre for certain specialised care, e.g. in pediatrics, and is one of six teaching hospitals with medical education in Sweden. In 2017, the hospital had a turnover of around EUR 1,6 billion and employed almost 17,000 co-workers (Sahlgrenska University Hospital, 2018).

The hospital’s top management has initiated an improvement project with the purpose of decreasing the queues to surgical operations by increasing the capacity without increasing the costs. The ambition of the hospital’s management is to take a holistic view of the problem and therefore, encompasses several aspects: organization and division of labor, education and staffing, IT and automation, production planning, and work environment and attractiveness as an employer. Further, the improvement project involves managers on all levels from first line managers to the division manager three steps up in the hierarchy. The project started in 2018 and it will finish in 2020. To sum
up, many of the aspects above are related to operations management and thus, there is a need to analyze the problem described above, with long queues and lack of capacity in surgical operations, with an operations management lens.

There are numerous scientific papers about application of operations management principles in healthcare and especially in operating theatres (Guerriero and Guido, 2011). However, as concluded by Holweg et al (2018), there is not a single underlying theory in operations management that can be used to analyse a process, instead there is ambiguity on which theories to use in operations management. Therefore, Holweg et al (2018) proposed the “process theory” and presented the 10 principles of operations management. However, Holweg et al (2018) make a point in the book to not present a comprehensive case or example of application of the complete theory, they refer to empirical evidence of the parts but not of the whole. To make the theory testable and practically applicable on an improvement project, there is a need to re-interpret the process theory to a design model. Therefore, the purpose of this paper is two folded, first to develop a model for re-designing processes based on the principles of operations management presented by Holweg et al (2018) and secondly to increase the understanding on how process design impacts patient queues, capacity utilization and costs in surgical operations.

Process re-design model
The base for the process re-design model are the ten principles of operations management as presented by Holweg et al (2018). The process re-design model is divided into two steps: the first step is to understand the current and the second step is to re-design the process. Further, the re-design part is divided into design, measure, manage and improve (see figure 1) also used by Holweg et al (2018). In the description below, the ten principles are related to the developed mapping rules (MR) and design rules (DR).

![Figure 1 – First current state analysis and second re-design the process](image)

Principles and mapping rules related to current state analysis
In order to improve and re-design a process, it is necessary to have a deep knowledge about current situation. This is done by mapping all processes including the tasks, inputs, outputs, resources and controls. The principles developed by Holweg et al. (2018) related to the developed mapping rules are principle #1, #2, and #3 (see figure 2).

**Principle #1 - all operations are composed of processes:** In order to improve operations, it is necessary to know the situation and map all processes including the tasks, inputs, outputs, resources and controls. The design mapping rule is:

- **MR1** *Map all activities in the processes:* Map all producing, supporting, and overhead processes including tasks, inputs, outputs, resources and controls

**Principle #2 - variation is inherent in all process inputs, tasks and outputs:** In a process, there will always be variation in quality, quantity and time and these variations can be handled by using extra time, inventory or extra capacity (Holweg et al, 2018). The mapping rules generated from principle #2 are:

- **MR2** *Identify customer needs:* Determine the customer needs for quality (minimum level), quantity, and timing for every customer process (averages and variation)
Variation in quality, quantity and time:

Measure averages and variation in quality, quantity and time for every process

Identify buffers (time, inventory, capacity):

Determine what buffering mechanisms that are used for every process

Principle #3 - work in process is determined by throughput-rate and throughput-time:
The throughput of the system is controlled by bottlenecks and the throughput-time of a process is stochastic (Holweg et al, 2018). The mapping rule is:

Identify present bottlenecks:

Identify static and dynamic bottlenecks for the present situation

Principle #2 - variation is inherent in all process inputs, tasks and outputs:
(description see above). The design rule is:

Dimension buffer sizes (time, inventory, capacity): Dimension what buffering mechanisms needed to cope with the variation in the processes. Add time, inventory or capacity when demand is high and in critical processes. (also related to principle 3 and 5)

Principle #3 - work in process is determined by throughput-rate and throughput-time
(description see above). The design rules are:

Match throughput-times and throughput-rates: Re-design the processes to get throughput times and work-in-process that matches the needed throughput rates (capacity per time unit) on average over a long period of time (also related to principle 3)

Identify future bottlenecks: Identify static and dynamic bottlenecks for future production scenarios. If more capacity is needed, run improvement programs that chase the bottlenecks.

Dimensioning the buffer sizes (time, inventory, capacity): Dimension what buffering mechanisms needed to cope with the variation in the processes. Add time, inventory or capacity when demand is high and in critical processes. (also related to principle 2 and 5)

Principle #4 - complexity in process design amplifies managerial challenges:
A simpler solutions will outperform a complicated one and the complexity will be a function of static elements, their heterogeneity and dynamic interactions (Holweg et al, 2018). The design rules related to principle #4 are:

Reduce unnecessary processes: Reduce complexity by removing unnecessary processes and tasks

Standardize processes and tasks: Reduce complexity by standardization of processes and tasks

Simplify dynamic interactions: Reduce complexity by simplifying dynamic interactions

Principle #5 - Process choice requires fit between the task and the external requirements: The possibility to specialized will be depending on the volume and variety of the processes (Holweg et al, 2018). The design rules are:

Specialize when low volume and variety: If the volume and variety is low, select processes and invest assets that are specialized and dedicated.
- **DR5 Match throughput-times and throughput-rates**: Re-design the processes to get throughput times and work-in-process that matches the needed throughput rates (capacity per time unit) on average over a longer time period. (also related to principle 3)

- **DR7 Dimension buffer sizes (time, inventory, capacity)**: Dimension what buffering mechanisms needed to cope with the variation in the processes. Add time, inventory or capacity when demand is high and in critical processes (also related to principle 2 and 3)

**Principle #6 - No single measure can capture the performance of a process**: It is important to use several performances measures but remember that the metrics are often dependent of each other (Holweg et al, 2018). The design rules are:

  - **DR9 Design measures for decisions**: Design measures based on the decision and information need of the organisation
  - **DR10 Measure all performance aspects**: Use several measures to capture all aspects of performance
  - **DR11 Use absolute measures**: Select absolute measures above relative ones

**Principle #7 - Process metrics can drive unintended behaviour**: You need to measure in order to manage, but on the same time you will get what you are measure (Holweg et al, 2018). This leads to design rule:

  - **DR12 Be aware of dependent metrics and behaviour**: You need to measure, but be aware of the dependences of performance metrics and design metrics to avoid unintended behaviour

**Principle #8 - Processes are improved by reductions in throughput time or in undesired variation**: There is a need for ownership of the processes, to work with continuous improvement and root cause analysis (Holweg et al, 2018). The design rules are:

  - **DR13 Ownership of all processes**: Make sure that all processes are owned and managed
  - **DR14 Continuous improvement resources**: Dedicate resources to work with problem solving and continuous improvement for all process (also related to principle 9)
  - **DR15 Reduce throughput-time and undesired variation**: Focus improvement efforts on reduction of throughput-time and undesired variation

**Principle #9 - The rate of process improvement is subject to diminishing returns**: In high performance processes, there are a trade-off between aspects of process performance, and these cannot be broken (Holweg et al, 2018). The design rules are:

  - **DR14 Continuous improvement resources**: Dedicate resources to work with problem solving and continuous improvement for all process (also related to principle 8)
  - **DR16 Continuous improvement vs process investment**: Perform continuous improvement until it is economically viable to make process investments
  - **DR17 Strategic prioritizing of performance objectives**: In a high-performance production system, a strategic prioritizing between performance objectives need to be made due to trade-offs

**Principle #10 - Processes do not operate in isolation**: There is always a risk for sub-optimisation in process improvement if you don’t take a holistic view (upstream and downstream processes) and focusing too much on one process can drive decisions and behaviours (Holweg et al, 2018). The design rule is:

  - **DR 8 Design with a holistic view**: Design with a holistic view of process interactions to avoid sub-optimum solutions

The principles and the design rules have many relations, see figure 3 to get an overview of all these relations.
The developed process re-design model

The developed process re-design model (see figure 4) is carried out in two steps: first to understand the current situations, by mapping all activities and their interrelation using the five developed mapping rules and second to re-design the process based on the thirteen design rules. The five mapping rules are group (current state analysis). The thirteen process re-design rules are grouped into design, measure, manage and improve. This is the same used by Holweg et al (2018).

Methodology

The first part of the purpose was to develop a model for re-designing processes based on the principles of operations management presented by Holweg et al (2018). To interpret the principles as design rules, the academic researchers had several meetings and discussions about design methodology based on experiences from application of design methodology in manufacturing settings and in healthcare.
The second part of the purpose is to increase the understanding how process design impacts patient queues, capacity utilization and costs in surgical operations. To answer this, the research team from the university is involved in an operational improvement project, in an action research arrangement, where the researchers are involved in data collection, analysis and in designing improvements. This improvement project following the developed process re-design model.

**Activity mapping**
The first step of the data collection was two activity mapping workshops where the first line manager together with experienced staff used an activity list developed for ward units and transformed it to a list of some 80 activities valid for the surgery unit. This list was then used as the foundation for both the process mapping and for the work sampling study.

**Process mapping**
The mapping was led by the research team and was conducted through a series of workshops with personnel responsible for different functions and processes. Between 2 and 6 persons attended each workshop and 8 workshops were conducted, 2 for the main process and 6 for supporting processes. The process maps were analyzed and clarified in a subsequent workshop with hospital staff from the project team and the final version was set after feedback on a meeting with the management. The project team analyzed all identified disturbances and bottlenecks and came up with recommended actions that were summarized in a report.

The process maps were documented using the IDEF0 method (NIST, 1993). It is a standard method that has been extensively used for a wide range of applications. The method has a structured notation with activities in boxes that are connected by inputs, outputs, controls, and resources. An input is something that is transformed by the activity to become the output. The input can be e.g. a sick patient or a dirty instrument that becomes a healed person and a clean instrument respectively. A control determines how and when the activity is carried out. Resources are needed to perform the activities such as people and machines.

**Work sampling**
The work sampling study (see e.g. Zandin, 2003) was carried out by two master students who were assisted by one assistant nurse that got training in conducting work sampling studies and handle the surf pad with a specific software for the task. A list of 31 activities were selected from the larger activity mapping list. In total were 4055 samples collected in 20 2h sample periods spread over 4 weeks. Only the day shift was measured and only staff belonging to an operations team and employed at the operating unit was included.

**Results – current state analysis**
A brief case description is followed by the results from the current state analysis which are structured according to the mapping rules (MR 1-5).

**The case**
The hospital has several surgery units with different specialties. The research case is carried out at a surgery unit specialized in stomach and intestine disorders. Colon cancer is the most common surgical operation at the unit. The unit has around 100 employees, not including the surgeons, and performs around 4000 operations per year. There are 10 operation rooms at the unit, of these are only five available for operations, due to staff shortage. The goal of the operational improvement project is to increase the capacity of
the unit by both open up more rooms and use the rooms for more operations per day, while not increasing the staff. The staff shortage has been worst for surgical specialty nurses, but the bottleneck staff category shifts over time. There are several other bottlenecks as well and the ambition of the project is to keep a systems view and encompass all important bottlenecks.

Each operating room is manned with an operating team consisting of the surgeon, an anesthesiologist, one nurse anesthetist (NA), one surgical nurse (SN) and one assistant nurse (AN). Sometimes, depending on the surgical procedure, one more SN or AN is needed. There are often different types of students present in the operating room, since it is a teaching hospital. The anesthesiologist is usually only present for a short while in the operating room and monitors several patients from another room. The surgeon is not employed at the surgery unit. Therefore, did the work sampling study only include the NAs, the SNs and the ANs in the operating team. There were other persons from the same three worker categories that handled supporting activities, such as production planning and coordination, material and pharmaceutical administration, and sterilization of instruments.

**MR1 Map all activities in the processes**

The process mapping workshops resulted in process maps documented using IDEF0. In total were 59 pages of IDEF0 process maps produced after some revisions and rationalization, initially there were over 70 pages. The maps include the main inputs to each activity and the output, but they do not in general include resources and controls. The resources are in most cases obvious and the controls were regarded as too time consuming to map in detail at this stage.

The main operating process is divided into:

- Pre-operative support process (activities to prepare for an operation before the patient arrives)
- Pre-operative patient process (activities to prepare the patient)
- Peri-operative process (the actual operation activities)
- Post-operative process (activities after the operation until the patient leaves the unit for post-surgical care)

The mapped supporting processes are the:

- Planning process
- Surgical instrument handling process
- Pharmaceuticals handling process
- Material handling process
- Education process
- Surgical equipment maintenance process

**MR2 Identify customer needs**

Two stakeholders can be regarded as customers to the operating unit, the patient and the society. The patients are a part of the society, but sometimes there are conflicting goals. The patient want treatment as fast as possible, while the society wants to treat the person with the greatest need first. Since the hospital is tax funded, there is also a focus on utilizing the resources as much as possible, which also can come in to conflict with the individual patient’s need. One need that is in common of both stakeholders is to shorten the long waiting lists, which was the background and motivation of the project at the hospital.
**MR3 Variation in quality, quantity and time**

The operating unit has good records of the quantity and quality the surgical operations performed. The time is planned using “operations cards”, which is essentially the process planning where all surgical and anesthesiological activities, and all material and instruments needed, are connected to specific surgical operations. This process planning is used in a production planning software “Orbit”. The actual operating time is measured and reported back to Orbit. The variation of operating time for different surgeons is taken into account to some extent in the production planning. Other time categories like preparation times and cleaning times are not measured. There is a planned time in Orbit, but the process mapping revealed that there was no one responsible for updating and maintaining these times. These other times, are sometimes as long as the actual operating time, which means that there is probably a great potential for improvement in the change over time.

The work sampling study was carried out to measure how much work time that was spent on different activities with the purpose of investigating the utilization of different staff categories. In the data collection was 31 activities used, however there were several activities that got none or very few samples. The summary in Table 1 is a reduction of the original list to only 12 activities, where the smallest activities have been joined to form larger activity groups. The activities are further categorized in four categories and ordered by size for each category.

</tr>
</tbody>
</table>

The result showed that the staff spend 58,6% of the work time on actual operating activities. This was perceived as a good result, because the management feared that it would be lower. However, there is still potential to increase this time by reducing the time spent on change over activities, documentation and waiting. The paid break time was much lower than we have previously measured on ward units.

**MR4 Identify buffers (time, inventory, capacity)**

There is obviously a large “inventory” buffer of people waiting for their elective surgical operations. The patients act as buffers on shorter time scale as well. If an operation is cancelled due disturbances, the patient will be put in the buffer again and sent home,
which on a personal level for patient is very inconvenient and prolongs the patient’s suffering. From the patient’s point-of-view would a capacity buffer been much better.

**MR5 Identify present bottlenecks**

Bottlenecks were discussed in the process mapping workshops, with focus on disturbances that the staff experienced in the work. These disturbances and their causes were documented on the process map connected to the activities they affected. In total were 36 action points identified that will have impact on the capacity by affecting different bottle-necks.

**Results – Process re-design**

The process re-design phase has only started up at the time of writing this article. The redesign activities have focused on three areas with potentially large impact on the capacity:

1. The changeover time between surgical operations. A method study of the preparation activities has commenced, a new cart for sorting trash directly in the operating room will be tested and the work of cleaning the operating rooms will be better synchronized to the production schedule.
2. The planning procedures will be revised, and staff schedule data will be used in the planning software, in order to use the optimization functions already available but not used. The changeover times will also be measured and used to update the “operation cards”.
3. The most important disturbances will be handled. This includes late changes of the operating schedule due to different reasons. Some reasons are internal but hard to affect (e.g. someone that can’t easily be replaced calls in ill the same day), some are internal and easy to affect (e.g. the surgeon hasn’t checked all the details of the case in time and decides on late changes). Some causes are internal to the hospital, such as lack of in-patient beds due to staff shortages at care wards, while some causes are external, such as that the patient hasn’t followed the instructions and had breakfast when he shouldn’t had eaten anything.

The improvement project will continue for another year, and hopefully there will be new culture of continuous improvement focusing on improving capacity by decreasing complexity, shorten lead times and lower variations.

**Discussion**

When it comes to the improvement actions and re-design of the operations at the unit, there is much to learn from the research literature. For example Meredith et al (2011) have analyzed the changeovers effect on efficiency and Fügener et al (2017) have recognized the importance of single surgeon’s behavior on the capacity. As mention in the introduction, is the study of operating units very common in scientific literature. This is probably due to the fact that an operating unit has a very clear production objective with easily measurable inputs and outputs. However, this study has demonstrated the need to go into deeper detail and analyze each activity and all processes to understand the complete problem and the important interactions within the system. There are no single or isolated action that will have any significant impact on the capacity, since there is a multitude of dependencies and interactions.

The methodological approach in this project has been a very traditional work study approach and work studies goes back to the origin of operations management. Even though Holweg et al (2018) don’t write about work studies, they point at the need for
detailed information about activities, times and variation. Consequently, in order to achieve a real impact on work places, there is a need to get into the details of the operations and applying the classical work study methods is still a very useful way of doing that.

The developed process re-design model, based on the operations management principles by Holweg et al (2018), has shown its practical use in the improvement project at the hospital. The mapping and design rules helped to structure the improvement project and communicate the need for the different current state analysis steps. So far, we have only begun to follow the re-design phase’s 17 rules. The application of those will be the material of forthcoming articles.

**Conclusion**
There is a demand from within the professional healthcare organizations that operational and organizational changes must be evidence-based. “Process theory – The principles of operations management” is the closest to evidence-based practice that our research field has come up with to date.

This paper contributes to the operations management theory by validating the applicability of the principles of operations management. The process maps and the work sampling result have laid the foundation for the analysis of the problem situation and several improvement areas have been identified. The design model has the potential to be used for all kinds of operational re-design problems in any context.

Abstract
The purpose of this paper is to outline pros and cons of cancer care pathway (CCP) components perceived by health care professionals involved in the diagnostic process. The results are based on a comprehensive national survey. The biggest pros follow from the component of care pathway description, which make cancer diagnostics more process-oriented and standardised and thereby contribute to more timely, safe and patient-centred care for the CCP patients. The component of standardised criteria for referral are associated with most cons. The biggest cons are the perceived “crowding out” effects, which imply impaired access and longer waiting times for non-CCP patients.

Keywords: Care pathways, Cancer care, Quality Management in Health Care

Introduction
Improvement of health care structure and management to deliver a high-quality care to acceptable cost is an important priority for health care systems (WHO, 2016). Advances in medicine and technology have helped to make a significant progress in diagnostics and treatment of many diseases, but also contributed to highly fragmented care processes. Due to specialisation, critical tasks in health care delivery are distributed across several care units with its own objectives, responsibilities and capabilities (McDonald et al., 2007, Berwick et al., 2008). Care processes often involve several transitions between primary care and specialist units, and many handoffs between health care professionals. Processes, that if uncoordinated, risks leading to lack of continuity and thereby ineffective and unsafe care with long waiting times (Stiernstedt, 2016, Bodenheimer, 2008).

In order to address these problems, care pathways are increasingly implemented as means to support more organised and efficient care based on evidence (Rotter et al., 2010, Vanhaeckt et al., 2009). A care pathway is defined as a care plan that specifies the ideal
sequencing and timing of interventions for patients with a specific clinical condition (Campbell et al., 1998). It guides clinical decisions in the process best suited for managing a particular health problem and increases the certainty of what to do in a given medical situation. Care pathways also help bringing together interdependent health care professional and teams that contribute to a common goal, such as when patients receive care from multiple providers (Singer et al., 2011).

Cancer Care Pathways (CCPs) are implemented in the Swedish health care system since 2015 and are considered crucial for supporting high quality, safe and effective clinical practice (NBHW, 2015). The primary purpose is to shortening the time from cancer suspicion to initiation of first treatment since early diagnosis and treatment are crucial to improve survival chances. In addition to faster diagnostics, CCP also aims to contribute to more equitable cancer care and improved patient satisfaction (Wilkens et al., 2016).

The Swedish health care system is decentralised with 21 independent regions, which implement CCPs for the nationally defined diagnoses. The implementation is based on nationally developed guidelines, but it is the individual region that is responsible for creating an organisation and ensuring resources that enable implementation and sustainable achievement of outcomes. The national follow-up of the implementation efforts show that regions choose different approaches to operationalize the CCPs in their local health care systems (NBHW, 2018). Implementations of care pathways usually include people and principles governing the flow of patients and information and it is supported by a range of measures as standardised communication procedures, clarification of responsibilities, active handovers, decision support tools, clinical information systems, coordinator roles and multidisciplinary work (Vanhaecht et al., 2010, Schrijvers et al., 2012).

The core of the CCP development program in Sweden constitutes on five components. 1) Standardised criteria for referral describe alarm symptoms for well-founded suspicion of cancer for each cancer diagnosis and constitute the entry key to CCP. 2) Coordinator role were assigned to ensure continuity in the diagnostic process and avoid unnecessary waiting times. 3) Care pathway description define the sequence of diagnostic activities and maximum waiting times. 4) Pre-scheduled appointments block time slots for appointments and investigations to ensure that CCP patients can be diagnosed within time limits. 5) Multidisciplinary conferences (MDC) should be carried out at end of the diagnostics process to evaluate the patient’s status and make a multi-professional decision on treatment. Hence, the purpose of this paper is to outline pros and cons of CCP components perceived by health care professionals involved in the diagnostic process.

Frame of references
The concept of care pathways has its roots in Total Quality Management, Critical Path Method, Business Process Redesign and Theory of Constraints (Mould et al., 2010, Schrijvers et al., 2012). Health care has typically a functional organisation requiring the patient to move between care providers with waiting times between visits (Bohmer and Lawrence, 2008). Care pathways imply a process-oriented organisation where the different tasks that need to be carried out by health care professionals are defined, sequenced and standardised for a specific group of patients (Mould et al., 2010). Process standardisation is considered a key for quality improvement as it helps achieving consistency, predictability and control over the material and information flow (Deming, 1994). In health care, it facilitates the movement of the patient and information, reduces
ambiguity, and provides more integrated care among health care providers (Bohmer and Lawrence, 2008).

The advantages of care pathways include shortened lead and waiting times, reduced fragmentation of care, improved efficiency, and increased patient satisfaction (Mould et al., 2010, Schrijvers et al., 2012). In Sweden, the goal of the CCP implementation is to improve the quality of cancer care as defined by the six underlying requirements: patient-centred, safe, effective, efficient, timely, and equitable (NBHW, 2006, Institute of Medicine, 2001). The CCP components, *standardised criteria for referral* and *care pathway description* (defining sequence of diagnostic activities) help to deliver more uniform and predictable diagnostics processes and thereby contribute to more safe, effective, efficient, and equitable care. Guaranteeing *pre-scheduled appointments* and setting maximum waiting times aim to assure more timely care. Finally, implementing *coordinator roles* and *multidisciplinary conferences (MDC)* should, among others, extend the communication with the patient, support patient involvement and thereby increase patient-centeredness (Schmidt et al., 2018, NBHW, 2015).

The disadvantages of care pathways comprise decreased flexibility, reduced job satisfaction due to increased time pressure, decreased autonomy and variation in work, and increased costs to manage and control the process (Schrijvers et al., 2012). Standardisation in health care is often also associated with reduced choice autonomy. Physicians are highly trained individuals who are used to act on their own decisions, and standardisation place limits on their freedom to practice as they prefer and to treat patients based on their professional experiences (Timmermans and Berg, 2003).

CCPs are also implemented in other countries such as Denmark, Norway and the United Kingdom (Håland and Melby, 2016, Jensen, 2015, NICE, 2011). One of key concerns surrounding care pathways there is that they are inflexible and insensitive to individual patient variation and needs. The common criticism is that if health care professionals are required to follow care pathways it might imply that patients’ individual needs go unmet or are inappropriately addressed (Håland and Melby, 2016). Further, both Swedish and Danish experiences show that the implementation of CCPs may lead to longer waiting times for other patients, which share the same resources as CCP patients (Smeds and Poksinska, 2018, Jensen, 2015).

**Design/methodology/approach**

This paper is based on a quantitative online survey. The survey is part of the national evaluation of CCP implementation in Sweden and was conducted in cooperation with the National Board of Health and Welfare. Data were gathered in four regions, which vary in size and geographical location and are characterised by different implementation strategies for CCP. In total, Sweden has 21 regions and the four selected regions represent almost one quarter (~23%) of the total Swedish population. The survey was sent out to 981 professionals and resulted in 359 responses, which makes a response rate of 36%.

The survey was directed to professionals working with diagnosing cancer in pre-selected CCPs. Respondents belong to three health care professionals’ groups: *doctors from patient care units* (medical, oncological and surgical) (48%), *nurses for support and coordination* (28%), and *doctors from diagnostic units* (e.g. pathology, radiology and colonists and endoscopists) (18%). There was also the possibility to choose “other”, which included respondents with mixed background as, for example, doctors in combination with the coordinator, specialist dentists, doctors in palliative medicine and nurses at cytostatic reception (6%). The selected respondents received an email with a
request to fill out the survey by the end of April 2018. After sending two reminders the data collection was closed by the end of August 2018.

In most of the questions the respondents received a predefined set of statements and were asked to indicate the degree of agreement based on a Likert scale with five points from 1 (not at all/not important at all) and 5 (to very high extent/very important). The data were analysed with SPSS Statistics 24. Descriptive statistics as well as ANOVA were used. The free text answers were categorised by themes, which were identified in an iterative process during the analysis. When the categories were set all answers were reviewed and categorised by at least two researchers. Some free text answers were long and could belong to several categories.

**Results**

The survey provides insights into a number of pros and cons of the five CCP components: *Standardised criteria for referral*, *Coordinator role*, *Care pathway descriptions*, *Prescheduled appointments*, and *Multidisciplinary conferences (MDC)*. Respondents were asked to grade the importance of the components for achieving better cancer care processes. The result shows that they are quite equally important, see Table 1. Standardised criteria for referral and multidisciplinary conferences were considered somewhat more important.

**Pros of CCPs**

The pros of CCPs were, among others, captured by the evaluation of CCP’s improvements as perceived by health care professionals. Respondents were asked to evaluate to what extent they believe that CCPs have contributed to a number of improvements, see Table 2. The respondents found that CCPs make the biggest contribution to a *more efficient diagnostic process* with significant differences between contact nurses being most positive and doctors from care units being least positive. *More satisfied patients* and *shorter waiting times* are equally ranked on the second place followed by *increased collaboration within specialist care* and *more equal cancer care*. CCP’s contribution to *increased collaboration between primary care and specialist care* is judged somewhat lower compared to collaboration within specialist care. Lowest ranked by the professions is the CCP’s contribution to *more individualised cancer diagnostics*.
The analysis of the free text answers provides valuable insights into the quantitative evaluation of the CCP's contribution to improvements. Table 3 presents the pros of CCP sorted by the number of free text answers included in the different pros’ categories. The mostly commented aspect was promptitude, describing the positive effects related to access, waiting times and lead times for CCP patients. Standardised sequence of diagnostic activities and increased coordination are considered to reduce the number of visits and thereby reduce the lead times. CCP patients benefit from prioritisation and pre-scheduled appointments as the waiting times for investigations are shorter and diagnostic process goes faster. Next category, stable and predictable processes contribute to more efficient and safer care for CCP patients. The responsibilities become clearer and improved coordination and collaboration, which is believed to reduce the risk of patients falling between the chairs.

The increased process orientation, which was implied in the CCP implementation, was recognised as useful to redesign the current working practices and achieve more structured and predictable diagnostic processes. This initiated also process work at various levels of the health care system. Further, the prioritisation of the CCP patients is believed to contribute to more equitable cancer diagnostics. Equity does not necessarily mean that all patients have the right to receive care equally quickly. Rather, it means that all patients receive assessments and care of equal quality at the right time based on their needs. Another example provided on improved equitability is that the diagnostic processes became clearer and unified across the regional health care systems. Respondents also commented on the increased awareness of different problems as waiting times, shortcomings in routines and bottlenecks in the system. This has led to many discussions and several improvement projects.

Next category of comments describes better conditions for increased cooperation around patients, see Table 3. All competencies within different specialties can be involved and can contribute to the investigation through MDC and cross-professional collaboration. The process work contributed to better communication and collaboration between clinics and hospitals, but not between primary care and hospital care. The contact between primary care and hospital care takes primarily place through referrals which were often not sent according to the CCP standard and commented by several as a development area.
The last category includes free answers that describe different aspects contributing to increased patient satisfaction. The perception is that the patients appreciate both faster and more coordinated care, which reduces potential anxieties for patients.

</table>

**Cons of CCPs**

There are also several cons identified from the questionnaire, which are presented in Table 4. The crowding out/impaired access for both non-CCP cancer patients and other patient groups stands out significantly more than other cons. In questions about disadvantages and associated impacts for other care areas or patient groups, 38 percent of all comments (193 out of 504 part comments) deal with “crowding out” effects. As CCP patients received priority, but share resources with other patient groups, the perception is that non-CCP patients have impaired access and longer waiting times for care. The “crowding out” also emerge because of the increased number of cancer diagnostics, which is the second mostly mentioned negative effect. Too broad criteria for referral are considered to contribute to that. The perception is that the number of cancer diagnostics has significantly increased, but not the number of cancer diagnoses. CCP is therefore considered to be resource-intensive in relation to the benefits generated. The criteria for referral form a large funnel that also captures quite healthy patients who don’t need cancer diagnostic and are unnecessarily anxious about cancer suspicion.

Excessive administration is the next category of cons associated with the requirement for coding and follow-up of lead times. Changed referral routines are also described as an aspect that contributes to administrative hassle and takes unnecessary time. Several respondents point out that CCP involves extra administration since the IT-systems are not compatible with process-oriented way of working. It all causes stress for the staff and takes time from the patients.
Increased workload is also a recurring theme in the free text answers since the introduction of CCP is considered to increase production levels. Too broad criteria for referral are perceived to increase patient flows and unnecessary tests and examinations.

Even though shorter lead times are mentioned as something positive several also comment that there is far too much focus on shorting lead times. The diagnostics process is shortened, but patients need to wait longer for treatment. It is also considered that the diagnostic process may go too quick so patients have not been able to reflect on the situation and are not always mentally ready for the next step.

The last category is faulty referrals. It is mentioned that there are both incorrect and incomplete referrals due to uncertainty in how the criteria should be interpreted and that CCP can be used as a quick path for patients who do not fulfil the criteria.

### Analysis

By the analysis it has established a connection between the CCP components and the pros and cons presented in the findings. However, the empirical material is so comprehensive that it is out of the scope of this paper to describe all examples brought up by the respondents. Anyhow, the purpose of the analysis is to show in what way the CCP components contribute to the perceived pros and cons. The results are presented in Table 5 and described in the following sections.

The most important but also the most questioned component of CCP are *standardised criteria for referral*. Alarm symptoms are defined for each cancer type and constitute a basis for referral. The referral criteria are however criticised for being too inflexible and leading to waste of resources. The criteria for several cancer types are considered too broad, which contributes to increased number of cancer investigations and capacity problems in diagnostic units. This implies an increased workload and stress for health care professionals. An advantage of referral criteria is that they contribute to more equitable care, since vulnerable patient groups have higher chances to be referred and benefit from fast-track diagnostics.

The *care pathway descriptions* contribute to the consistency and predictability of work processes and makes the system less dependent on individuals. The diagnostic process is
perceived as more integrated, coordinated and quicker. The pros are enhanced communication, improved collaboration around the patient and more seamless transitions between care units. The care pathway descriptions contribute also to more equitable cancer diagnostics across hospital and regions. Maximum waiting times included in the care pathway descriptions contributes to the pros of promptitude. However, too much focus in the care pathways descriptions is placed on waiting times, which cause several cons. First, a quicker diagnostic process is also not always better. The strong focus on lead times can make that other patient needs go unmet. Second, resources are wasted on following waiting times. The administrative work is considered cumbersome and taking time from patients. Third, CCPs can be misused to push non-CCP patients through quicker diagnostics.

The pre-scheduled appointments prioritize CCP patients and contribute to more timely diagnostics. The drawback is that patients cannot always benefit from getting quicker diagnosis as they may need to wait longer for treatment. Some patients may not be mentally ready to go through diagnostics quickly. The pre-scheduled time slots may also cause that appointments are lost for other patients.

Coordinators are perceived as a valuable resource that contributes to more patient-centred care and supports coordination and administrative work. They are an important means for patient contact so that not only patients’ medical needs, but also psychological needs are met. Coordinators have also an important role to support weak patients and navigate them through the diagnostic process. An important work assignment is monitoring patient status, which implies a significant workload as the IT systems are not suited for the process-oriented way of working.

Multidisciplinary conferences create opportunities for different specialists to evaluate individual patient cases and develop a joint recommendation for treatment. MDCs contribute also to an improved cooperation as the involved health care professionals get to know each other and get an increased understanding about the different professional perspectives on cancer care. The cons include increased workload since the preparation for and carrying out MDCs requires extensive resources in terms of time and personnel.

Some pros and cons are difficult to assign to a single component, but they result from CCP implementation as the whole concept. An example is that CCP contributed to better insights into bottlenecks, waiting times and shortcomings in routines and resulted in process improvements at various levels of the system. A perceived negative effect is that the prioritisation of CCP patients and the increased number of diagnostics led to longer waiting times for other patients. This is the most widely discussed negative effect in the survey.

Conclusions
As expresses by one respondent CCPs provide “more pros than cons but still there is a lot of to improve”. The biggest pros follow from the description of pathways, which make cancer diagnostics more process-oriented and standardised and thereby contribute to more timely, safe and patient-centred for the CCP patients. The biggest cons are the perceived “crowding out” effects, which imply impaired access and longer waiting times for non-CCP patients. Standardised criteria for referral are associated with most cons, a component that can be a subject for revision and may improve over time.

Abstract

Although a straightforward relationship seems to exist between the ‘objective’ length of waiting time and the more ‘subjective’ customer experience it has also been recognized that individuals do have different time perspectives. In this study we explore the role of time perspectives in order to better understand how hemodialysis patients experience time during a time-laden service, i.e. the process of transportation from home to the hospital and back. In our findings we found a distinction between patients in terms of hurriedness and social orientation while being transported. As such dialysis patients exhibit different timestyles or time personalities.

Keywords: time personalities, waiting time, patient transportation

Introduction

In the field of service operations management, there has been since many years attention for waiting times. A recent article summarizes the strategies to manage queues to reduce the discomfort experienced while waiting: (1) eliminate or reduce the wait through process enhancements, (2) manage expectations through timely and relevant communication with one’s customers, and (3) enhance the waiting experience (Weiss and Tucker, 2018). Although these strategies are based on the well-known operations management and psychological approaches for managing waiting times, they do not necessarily take into account the complexity of the time concept. In this study of waiting time in the process of patient transportation, we link the more traditional operations management view on time with the more recent findings on temporal variables in organizational science.

Background

The OM and psychological approaches for managing waiting times are based on the classical distinction between objective and subjective time in the time theory. Objective time or clock time is usually what people answer to a question “what is time?”. Shipp and Fried (2014) defined clock time as a view of time that is (a) unidirectional—progressing
from past to present to future, (b) homogeneous—each second is the same as any other second, and (c) absolute—time is the same across all situations and individuals. In contrast to objective time, subjective time (psychological time), is described as “(a) cognitively cyclical—thoughts may move between past, present, and future in any direction; (b) heterogeneous—some moments pass more quickly than others; and (c) interpretive—experiences can only be understood in context” (Shipp and Cole, 2015, p. 239). Subjective time is integral to the experience of being human. It is “merely our word for the movement of events and sensations through us” (Burdick, 2017, p. 369).

Although a straightforward relationship seems to exist between the ‘objective’ length of waiting time and the more ‘subjective’ customer experience (Pruyn and Smidts, 1998), it has also been recognized that individuals do have different time perspectives (Shipp et al., 2009), i.e. the overarching view that an individual has towards various aspects of time. These time aspects are defined in terms of different temporal variables such as temporal structure, temporal focus (Shipp et al., 2009), hurriedness (Conte et al., 1998) and others.

In this study we explore the role of time perspectives in order to better understand how hemodialysis patients experience time during a time-laden service, i.e. the process of transportation from home to the hospital and back. One might expect that patients do not want to spend too much time in this supporting process. Nevertheless, how patients do experience this transportation time can be different based on their time perspectives. This study aims to explore what kind of temporal variables can be recognized in this process and how the transportation process can be designed to better fit these personalities.

**Methodology**

First a literature study on waiting times in healthcare services and time perspectives was conducted. Empirically, we carried out a case study, primarily due to the exploratory nature of the research (Yin, 2014). Multiple sources of data collection have been used such as documentation, archival records, interviews and direct observation. Thanks to these multiple sources, findings and conclusions are likely to be more accurate and in this way the case study will substantially increase in quality (Yin, 2014).

The dialysis center of a general hospital was chosen as case. This center was selected because they were currently investigating how the transportation process of patients could contribute to improvements in the process of hemodialysis treatment. The center was facing an increase in the number of patients having dialysis which can be explained by higher life expectancy and the more successful treatment of cardiovascular morbidity. Most patients have dialysis three times a week. In Flanders, more than half of patients having dialysis in 2013 had an age older than 65 (De Meester, 2013). The main part of the patients comes to the dialysis center with “collective transportation”. Both small with less than 5 vehicles and larger taxi firms are involved, offering individual or collective (in group) transportation.

In this research qualitative interviews are held since the focus lays on the interpretation and experience of the respondents. The method used is in accordance with the Consolidated Criteria for Reporting Qualitative Research (COREQ) and will be presented as such (Tong, 2007). Based on a topic list derived from the literature studied, we conducted 75 semi-structured interviews: 50 patients, 11 drivers (from 7 taxi companies), 9 dialysis nurses, 2 assistant head nurses and 2 employees from the hospital’s social department. Besides, observations and analyses of documents facilitated a process of triangulation.

The study of contemporary phenomenon in its real-life context obligates several ethical practices such as gaining an informed consent. All respondents were asked to sign an informed consent before the interview to inform them of the nature of the case...
study and formally soliciting their willingness to participate in the study. The interaction with human subjects in the study take place through both direct contact (as in interviews) and indirect contact (patient records). For both kinds of data collection permission is obtained by the Ethics Committee of the two hospitals involved in the study.

Results

Results of patients’ interviews

At the start of the interviews, patients were asked if they were satisfied or rather unsatisfied with their transport to and from the hospital in general. The opinions were divided equally: 48% of the patients responded to be rather satisfied about their transportation whereas 52% feel unsatisfied. The aim of the remainder of the interview was to clarify this 50/50 relationship and more particularly the role of time.

When asking about the time patients had to wait at home, 33% of the respondents stated that the driver picked them up on time. 45% had to wait in average between 0 and 15 minutes, 18% between 15 and 30 minutes and 2% longer than 30 minutes. Only one patient said that the driver tended to pick her up too early: “They pick me up too soon at home and too late at the hospital. I’m away from home for 7 hours, that’s a long time without having lunch” (Patient respondent 39). When patients asked the reason of the tardiness they found it difficult to believe the excuses since drivers tended to repeat the same excuses, such as traffic jams or having to drop off another patient first. Several patients mentioned that drivers had already forgotten that they picked them up on an earlier occasion.

![Average waiting time at home](Image)

After dialysis, 11% of the patients did not have to wait at all because the driver was already present in the waiting room before they arrived. 34% of the patients had to wait less than 15 minutes, 17% between 15 and 30 minutes, 19% between 30 and 45 minutes, 13% of the patients more than 1 hour. When asking how the respondents experienced this waiting time, 71% responded they found it comfortable: “We see each other several times a week, it is nice to get to know each other. By spending some time together in the waiting room, we become a kind of family, that’s something beautiful” (Patient respondent 44). After dialysis, 81% found the waiting time normal but only 55% found it acceptable. Many patients had understanding for having to wait for their driver: “I go home after dialysis, so I do not mind if I have to wait for 15 minutes. I understand that this is different for people who live in a retirement home” (Patient respondent 48). Patients were sometimes mad on the driver if he was running late, even though this was not always the driver’s fault. They never saw the dispatcher (only in case of a small taxi firm with the dispatcher also being the driver), so if they wanted to complain, the driver was the first person to address.
Furthermore, patients complained about the time they had to spend in the car. Some patients were sharing a taxi with 4 persons so that the time spent in the car (one way) could mount up to 45 minutes: “They try to put as many patients in one car so it becomes profitable for them, but that is less comfortable for us. They should know their priorities; the patients or the money?” (Patient respondent 44).

Results of nurses’ interviews
Some of the findings of the patients were also confirmed by nurses. Several nurses made the remark that not only time spent in the waiting room but also time spent underway in the car can be very long for a considerable number of patients. “There are patients who spend more than one hour in the car. Most of the patients are old and are tired after a dialysis treatment. The dialysis days can be very long and exhausting for these patients, and this several times a week. A patient having dialysis can be compared to a person running a half-marathon” (Nurse respondent 8).

An assistant head nurse remarked that not all patients complained when something went wrong. Several patients just waited patiently while others complained directly: “Some patients have a strange notion of time; there are patients who are in the waiting room for 5 minutes and start complaining of being there for 30 minutes. Other patients are satisfied about their driver and know him, they don't mind having to wait.”

Results of drivers’ interviews
Also drivers recognize the problem of tardiness: “Sometimes there is a lot of traffic causing delays. The same trajectory I normally do in 15 minutes can take up to 1 hour in that case” (Driver respondent 7). Multiple drivers also quote that the punctuality of the patients after the treatment depends on the day of the week, on the nurse and on the shift. One driver experienced the biggest tardiness problems when picking up the patients in the morning session. In this respect the drivers of large taxi companies claimed to have an advantage compared to the small firms: “When a patient isn’t ready on time we communicate this to the dispatch. They check with the other drivers who will also drive to the hospital and can pick up that patient later. In this way the patients are moved last minute to another schedule. Also, when we dropped off a patient too late this is communicated. In this way the dispatcher can take into account that this patient will probably finish later as well” (Driver respondent 4).
Taxi companies could be classified into two main types depending on the number of cars. Small firms tended to have a limited number of dialysis patients. Most of the time, the same driver did the same route with the same patient. Patients that mentioned always having the same driver, all drove with a small company. This type of taxi had several advantageous features, for instance, the fact that driver and patient started to know each other well. This boosted the communication between both parties and created understanding for tardiness. For patients in possession of a phone, the driver had the possibility to contact these patients if he was running late. Several patients and also nurses mentioned that if they knew why the driver is late, they would not worry about whether or not the driver had forgotten about them and this would create an entirely different kind of waiting atmosphere. In this way the communication had an influence on the waiting time experience.

Bigger firms had a large number of dialysis patients and a large number of drivers. As a consequence, patients did not have a fixed driver. 82% of the patients mentioning they had many different drivers, were driven by a large taxi firm. The biggest advantage of these large firms was the opportunity to make last minute changes in the schemes to switch patients from one driver to another. This prevented drivers of having to wait at the hospital. The taxi firms were paid per trip so standing still was a waste of time and money. An unpleasant characteristic of these larger firms was the lack of a relationship between driver and patient. Drivers came to the waiting room of the hospital with only a name of the patients they wanted to pick up, without knowing the conditions or situation of these patients at all. More than half of the patients who had been forgotten to be picked up, were driven by one of the larger companies. Drivers of these larger firms acknowledged his problem and saw last minute changes in schedules as the main cause. If one compares small and large taxi firms on satisfaction, 91% of the patients who were served by a small taxi firm said to be satisfied while this was 64% for larger firms. Furthermore 85% of the patients served by small firms accepted tardiness while this was 77% for the large firms.

Discussion
The interviews show that many patients are rather unsatisfied with the current organisation of the collective transportation to and from the hospital. The main reasons are long waiting times and miscommunication. Patients have complaints primarily about the waiting time after the dialysis. 38% of the patients that use transportation have to wait regularly more than 30 minutes before being picked up by their driver. 13% of the patients even have to wait more than one hour after the dialysis. Regarding communication, the major problem is that the dialysis center and the driver do not communicate enough in case of delays or changes in the schedules.

Our results also show two groups of patients with different characteristics (Table 1). The groups differ in terms of how they look at different aspects of time, more specifically waiting time, time in car or process time and the on-time performance (e.g. tardiness). Durandeeau et al. (1999) describe the general attitude towards time as time styles and were one of the first to link the time styles of service customers to their experience of waiting. They conclude (p.183) that “more and more diversity exists in the way people perceive and manage their time, and individual differences in terms of time styles influence a number of time-laden consumer services (such as financial services).”

In this study we find evidence that the transport of patients is also a time-laden service where differences in terms of time styles affect transitional factors when the customer waits for the service. For instance, patients differ in their concern with the passage of time, or are less or more hurried. Hurriedness, as a dimension of timetyles, is the general tempo of an individual’s activities being fast or slow (Shipp et al., 2009). A fit between
the general tempo of an individual and of the group they belong to can create satisfaction (Jansen & Kristof-Brown, 2005).

The studies of Usunier and Valette Florence (2007) and Durrande- Moreau and Usunier (1999) further support the view that people have a general tendency to perceive and use time in a certain way that is characteristic of them. Furthermore, Cotte and Ratneshwar (2001) argued that timestyles are also described by a dimension of social orientation, which indicates the tendencies of preferring to spend time alone or to spend time with others. This social orientation seems to be an important characteristic of dialysis patients. In the present study this social orientation comes down to the distinction between ‘talkative’ and ‘silent’ patients. There is some indication that talkative patients who are not in a hurry prefer small taxi companies, allowing them to create a personal bond with the driver (see table 1).

Table 1: Characteristics of patient groups

<table>
<thead>
<tr>
<th>Prefer silence</th>
<th>Talkative</th>
</tr>
</thead>
<tbody>
<tr>
<td>Don't care about who drives</td>
<td>Prefer fixed driver</td>
</tr>
<tr>
<td>Don't like waiting</td>
<td>Don't mind waiting (= social contact)</td>
</tr>
<tr>
<td>No understanding for having to wait</td>
<td>Understanding for having to wait</td>
</tr>
<tr>
<td>Don't know the driver</td>
<td>Have personal bond with driver</td>
</tr>
<tr>
<td>Like to complain</td>
<td>optimists</td>
</tr>
<tr>
<td>Time in car = short (picked-up last, dropped-off first)</td>
<td>Time in car = long (picked-up first, dropped-off last)</td>
</tr>
<tr>
<td>Short time in waiting room</td>
<td>Long time in waiting room</td>
</tr>
</tbody>
</table>

As timestyles seem to be a multi-dimensional construct (Cotte and Ratneshwar 2001, Settle et al. 1978, Usunier and Valette-Florence, 2007), timestyle scales have been developed to capture these multiple dimensions (Usunier and Valette Florence, 2007). In further research these timestyle scales can be adapted and used to better understand the perception of the time dialysis patients spent in a taxi.

Conclusion
In the field of service operations management, there has been attention for waiting times since many years. A recent article summarizes the strategies to manage queues to reduce the discomfort experienced while waiting (Weiss and Tucker, 2018). Although these strategies are being based on the well-known operations management and psychological approaches for managing waiting times, they do not necessarily take into account the complexity of the time concept. Based on a growing body of literature on time personalities and timestyles in organizational science, we can much better understand how patients experience time. These insights can be used to better design services, e.g., patient transportation in line with the needs of the patients.

Management of complexity in the care system

**Abstract**

Managing complexity within care systems is an increasing challenge as levels of comorbidity and frailty grow within the population. This case study research examines, longitudinally, the sources, types and nature of complexity within a care system in the UK. Providing care professionals with a framework on how to categorise and develop approaches to managing complexity within and across professional boundaries.

**Keywords:** Complexity, Healthcare Management, Care

**Introduction**

Complexity is a growing area for research in operations, both in terms of its positive contribution as well as dysfunctional attributes. However, it is a poorly investigated area in health and social care. Increasing levels of comorbidities and fragmentation of services are significant sources of complexity faced by healthcare and social service professionals and their ability to deliver quality outputs (Aronsson et al., 2011). The concept of complexity within healthcare was only formally recognized by the U.K. Medical Research Council (MRC) on the production of guidance notes to develop and evaluate complex interventions in 2000. However, this original document, and its subsequent revision in 2008, was criticized for largely avoiding the specific question of what constitutes complexity in healthcare. The lack of clarity on definition has led to complexity being viewed as an abstract concept with limited relevance and fit for what managers need (Cohn et al, 2013). To embrace the opportunity of envisaging complexity at a system level, across multiple interfaces, healthcare and social service professionals have to evolve their comprehension of complexity and its management (Sturmberg et al, 2014).

Recently, manufacturing operations scholars have begun to research a dualistic approach to managing complexity. This envisions complexity in terms of properties, which can be reduced or accommodated to either minimize dysfunctional or embrace strategically important characteristics. A framework for managing this approach has been proposed (Aitken et al, 2016; Turner et al, 2018). Historically, managing complexity in care systems was done through reducing phenomena to constituent variables however, this approach ignores the interactions which are emergent and contingent upon one another as well as those aspects which remain uncertain (Nilsson and Darley,2006).
Differentiating between complexity which has negative or positive consequences, and the approaches to manage these characteristics, is an area that has not been investigated. This paper explores the possibility of this dualistic approach proffering a platform for health and social care professionals to manage an increasing challenging and difficult environment.

**Literature**

Operations researchers have explored the applicability of manufacturing derived concepts and models in service environments, as an approach to enhance the efficiency and effectiveness of the processes used to deliver customer value. However, within the care sector this approach has proven to be challenging and on occasions unsustainable (Lindsay and Kumar, 2016). The duality of patients being providers of their own inputs into the care system, as well as beneficiaries of its outputs, is viewed as being the most critical and challenging aspect of applying traditional operations management approaches to health care (Sampson, 2000). The patients’ dual role limits the care systems ability to build inventory and buffer against variations in arrival demand uncertainty, service process time variability, patients’ capability to interact with care being provided as well as capacity constraints (Aitken et al, 2016). Due to budgetary and resource limitations care system capacity, unlike commercial organisations, is not demand-led instead it is “resource-driven” leading to queues and an increased likelihood of service failure (Walley et al, 2013:887). Healthcare organisations attempt to manage non urgent demand on their systems by delaying the arrival of patients through utilising appointments and extending lead-times for scheduled operations and consultant visits.

Against the background of a resource-driven stance the care system is experiencing greater complexity in patient illnesses, treatment processes along with fragmented vertically integration across the organisation (Aronsson et al, 2011; Gehmlich, 2005). Addressing complexity through a reductionist approach has been the historical modus operandi of healthcare practitioners. Segmenting the patients’ illnesses into singular components has aligned with a resource-driven perspective which schedules capacity through availability and priorities. Recently, the sector has recognised that patient treatment is more complex than isolating and treating specific components of an illness rather they are “increasingly being forced to evaluate components across a range of different domains – bio-medical, organisational, psychological and social – all at work simultaneously” (Cohn et al, 2013:40). The comorbidity of patients and the need for multi-agent support has increased the complexity faced by care professionals in the delivery of a quality service challenging the resource-driven approach of the sector.

Operations researchers have studied and derived conceptual models to support practitioners in the management of complexity for over twenty years (Wilding, 1998, Bozarth et al, 2009. Turner et al, 2018). The ideas and frameworks which have been developed to categorise and manage complexity, we posit, could provide a basis for addressing the increasing complexity care professionals are experiencing within the confines of a resource-driven environment;

*Internal vs external generated complexity:* Literature within operations has sought to identify where complexity originates from. Internally complexity can be generated by quality issues, failures to conform to standards, diverse IT systems, poor process controls and organisational structures (Serdarasan, 2012; Manju and Sahin, 2011). Within healthcare these issues are also apparent and challenge care professionals in delivery of a quality service (refs). Externally issues across organisational interfaces such as customer demand variances or unclear specification of requirements (Bozarth et al., 2009). The
duality of a patients’ role, in being an input into the system as well as a direct participant in the care process and its performance, has the potential to increase the complexity within and across boundaries.

**Detail vs dynamic complexity:** Numerousness in a system drives detail complexity. Reflecting the number of customers, suppliers and components that are located within and across interfaces of an organisation (Bozarth et al., 2009). Within a care system this would include patients and their range of illnesses, medical suppliers, multi-care agencies and process interactions. Early research into complexity highlighted uncertainty as a major element of dynamic complexity. The interconnected nature of processes and their wider systems can impact performance at other points in unexpected ways (Bode and Wagner, 2015). For example, the bullwhip effect demonstrates how a small change in demand can be magnified across a system leading to significant changes elsewhere in the system. The concept of detail complexity was recognised in the 2008 MRC guidance that complex patient interventions consisted of several components. However, the guidance failed to identify the interconnectedness of the patient and their treatment to the wider ecosystem and that change in one component can provoke unplanned changes throughout the system (Thompson et al, 2016)

**Necessary vs dysfunctional complexity:** Recent literature has highlighted the dichotomous nature of complexity as it can be both a positive force for change as well as negative influence on efficiency and effectiveness (Turner et al, 2018; Aitken et al, 2016). For example, within operations management increases in product types or customisation can be of strategic importance when entering new markets yet, can cause inefficiencies within manufacturing as the frequency of changeovers grows. Similar juxtapositions are evident in the care system. Through increases in expertise and knowledge of how to prevent and treat illnesses patients are surviving and living longer. This positive development has led to a greater need for healthcare professionals to consider frailty levels of patients. At the extremes, long term conditions can mask frailty or patients with no precondition are accessed with a minor aliment which result in a rapid decline of health (Turner, 2014), which is challenging the effectiveness and efficiency of the care system.

The three themes identified are important to care professionals in the management of their processes and the delivery of a quality service. Comprehending the causes and types of complexity provides a basis for organisations to explore and design their potential responses. Firstly, identifying the source of complexity, internal or external, provides the opportunity for an organisation to determine how to manage the complexity to limit its deleterious impact on care process performance. Secondly, the different types of complexity, dynamic or detail, have differential impacts on operation and performance of processes and require different solutions. Thirdly, recognising whether complexity is dysfunctional and needs to be reduced or necessary, for a patients’ health and well-being, can guide care professionals on the appropriate approach to complexity management (Turner et al, 2018).

The operations and healthcare literature are in accord that organisations should focus on reducing complexity to diminish its dysfunctional impacts on processes (Mazzocato et al, 2014; Serdarasan, 2012; Manju and Sahin, 2011; Bozarth et al, 2009). Through a reductionist approach some individual components of a system can be standardised, variability minimised and controls increased (Aitken et al, 2010). However, not all complexity is deemed negative in nature requiring diminution as some aspects may provide differentiation and a competitive advantage in manufacturing (Fisher, 1997).
Similarly, the care sector through recognising that patients are part of a wider, interconnected ecosystem are embracing complexity in the management and support of patients. Comprehending that complexity can be important to businesses operation scholars have identified that the creation of slack resources (that can absorb increases in complexity) and investment in information systems or lateral relationships (providing the platform for an organisation to process information more efficiently and effectively) are two options that can be developed (Turner et al, 2018; Aitken et al, 2016; Galbraith 1977). Improving information systems and developing lateral relationships may also provide an opportunity to accommodate complexity across the care system. However, the resource-driven context faced by care professional may restrict the opportunity of developing slack resources.

Understanding the types and nature of complexity that exists within the care system and how it can be addressed and managed by care professionals is the focus of this research. The next section describes the methodology deployed to investigate complexity within a care system in the U.K.

**Methodology**

This single case study (Jankowitz 2005) employs an exploratory approach, supporting a detailed understanding of areas that are not well documented (Eisthenhardt, 1989) and without sufficient theoretical underpinning (Meredith, et al 1989). Understanding context, a strength of the case study methodology, enables a more expansive understanding of operational complexity. Further, multiple sources of data collection e.g. observation, semi structured interviews, documentation, enable systematic analysis of contemporary activity over time (Yin, 2014; Eisthenhardt, 1989) to provide insights which can be evaluated against literature.

The unit of analysis, within this longitudinally case study is the community care system and included participants from GPs (General Practitioners), Acute Hospitals, Community Hospitals, District Nursing and Social Services. The case study provided an opportunity to review the under research domain of community health care systems (Heaney et al, 2006) which is connected to acute hospitals and GP’s through the provision of rehabilitation (either in the form of after surgical care or enabling patients to be returned to their normal place of residence). The case study organization treats patients from both urban and rural communities and specifically is in the region where over 65’s are the highest in the UK. At the time of the study the health of the population served by the healthcare system is representative of the UK with the exception of weight (marginally higher) and the levels of exercise (marginally lower). Geriatrics average length of stay (LOS) in the acute healthcare setting was the worst in the region (although overall the LOS for all conditions treated in the acute setting was comparable to others in the region). The community care system was therefore selected for a improvement programme seeking to improve the performance (both within the acute hospital by providing earlier rehabilitation and within the case study setting).

The system selection reflects input, process, output proposed as the basis for operational theory development (Boer, et al, 2015). Patients were predominantly referred by either local GP’s or were discharged from the acute hospitals. The community hospital, as the system unit of analysis (process) consisted of four ward within a physical hospital boundary. The capacity of the community hospital was used flexibly although the wards were demined as two rehabilitation (28 and 30 beds respectively), one trauma and orthopedic (14 beds) and one stroke (28 beds). A purely clinical flow was rejected (i.e. care pathway) as this would have potentially diluted the observations related to operational complexity. In the system studied,
patients were discharged primarily to their homes. A discharge liaison officer was in post to facilitate this process.

Secondary data collection provided performance date, while semi structure interviews provided multiple actors to express and reflect on perspectives of operational performance versus how it felt to work in the case study environment. Participant observation of improvement workshops provided an opportunity to collect primary data and latterly validate research findings. Triangulation of collected, both qualitative and quantitative, and subsequent verification of derived findings are discussed in the next section.

Case Study

Community care systems typically provide a range of healthcare services where rehabilitation and specialist therapy intervention are most prevenient (Heaney et al 2006). The community care case excludes outpatient activities. The inpatient care provision is predominantly rehabilitation services to return patients to their place of residence and exclude maternity services. As with the acute hospital setting all patients, ideally, have a discharge plan in place at commencement of their episode of care. Discharge plans are designed to understand what treatment/outcomes are anticipated for the patient (internal to the organization) and which activities need to be initiated for the patient outside the organisation (down stream). The internal process flow of patient treatment is a function of different professional interventions and outcome of treatment(s). All patients referred to physiotherapist but not all were referred to occupational therapist. The medical team assess patients on alternate days.

Findings

GP admissions to the community hospital were predominantly arriving between 12-6, with admissions from acute hospitals arriving from 3-6 in the afternoon. Performance data showed that patients age range in the period studied is 10% are 65 or below, 50% are 81 or below, 80% are 89 or below.

Where patients where admitted with preexisting mental health conditions an additional member of staff was required to support their care. In the period studied 7% of admissions were coded to require this care package and a further 7% with a secondary coding of this nature.

Sixty-nine percent of patients were discharged, 14% were readmitted to an acute hospital, 11% died and the remainder were transferred to other community hospital. Of the total patient group 14% were discharged to nurse led care homes with just over 11% of these patients being determined as delayed transfers of care (DTOC).

Length of stay statistics for the period of study reveal that 7% of patient leave within 5 days, 20% of patient leave within 15 days, 50% of patients within 40 days, 80% of patients within 88 days. Length of stay is not a function of age with DTOIC including patients from 50 and upwards.

At conclusion of the research 13 patients had been at the community hospital for the year of study. There was variation in length of stay for all the different medical conditions. There was no real pattern in admissions and discharges, although activity dips at weekend.
Medical team ward rounds were alternate days and therefore may not pick up on rehabilitation patients at suitable time (potentially 2 days could be lost) because of the time of admission to the community. Further complexity could be highlighted at the medical team ward round related to co-morbidities, which would mean involvement of other professionals. Once the requirement for an occupational therapist was confirmed the lead time for an assessment was 7-10 days for OT assessment.

Specialist therapy’s reported delay in patients getting x-rays (up to 4 days) and computed tomography scan (up to 4 weeks) to aid decision making about treatment and recovery progress.

**Internal vs external generated complexity**

The case study revealed the level of internal complexity in the community care setting particularly around the discharge process, which rather than being a type of ‘standard operating procedure’ or checklist for good practice was moderated by the frequency of the medical ward round (equivalent to a set up in manufacturing) where the treatment plan was confirmed.

It was found that patients from the acute setting (upstream) could have provided input into the discharge plan at the community case as part of the hand over documentation for the patient. However professional standards require that an individual is professional liable for patient diagnosis and treatment and thus each professional will individually review the previous assessment.

The frequency of medical ward rounds becomes a feature of internal operational complexity. This complexity is then amplified as a consequence of arrival variation (from the acute setting) and discharge variation (external variation). The community care hospital worked to align capacity and demand to improve the flow and therefore reduce time routine patients needed to stay on the wards.

The finding from the case study was that 14% of patients were discharge back to the acute hospitals. This could be construed as a deviation against the discharge standard upstream. However a patient condition is not homogeneous and the management of technical quality need to be more akin to the repair and overhaul process within industry. The continual assessment of professionals is therefore an important part of quality. The proportion of patients returning to the acute hospitals suggested that there is also process quality issues i.e. what is a discharge standard upstream, where nurses reported ‘Inappropriate transfer of patients to free up beds in acute’.

**Detail vs dynamic complexity**

The different professional groups undertaking tests and investigations, therapies and clinical assessments means there are many differing voices in the assessment and discharge process. These different voices mean that variation is not just across professions but down to the individuals working at a point in time. The compounded with uncertainty regarding timing of discharge from the acute hospitals, the management of ambulance transfers and the readiness for the community hospital
to take patients is a function of uncertainty in operational capacity across the supply chain, and the overlapping of professional and personal standards.

Further complexity is then added if there are social considerations. In this case study, 14% of the patients were discharged to a care home and sixty-nine to their own homes. In the first instance, a social services package may either need to be invoked (for patients moving to a care home for the first time) or restored (for patients needing to return to a care home for the same or an increased level of care). In the second instance, it may be deemed that, while the patient may return to their own home, they may require enhancements to the property (stair rails, etc.) to improve safety.

Coordination across several organizations, involving many professionals and across a number of different medical conditions, was initially not recognized by those involved in the case study. There was no means to resolve conundrums although the different groups coming together did enable a better understanding of each others role. While change was adopted in the case study, management of DTOC still provide a level of complexity that is a challenge, because of the extra level of professional involvement with local authorities and different financial constraints and rules for social care.

*Necessary vs dysfunctional complexity*

While the professional complexity for treatment is deemed as necessary complexity the setting for the delivery of services is not. The ability to rehabilitate some of the patients in their own home (known as reablement) had been recognized by social services. Provision of a service package to avoid admission to the community care system had been made. Therapies been considered a necessary complexity for patient recovery i.e. therapies can only be offered in a community hospital setting. Breaking this view provided the potential for dysfunctional complexity to be removed. However as a consequence of the different groups of professionals housed in different functional entities this enhancement of service had not been well communicated. Since the research period and as a consequence of the improvement programme patients there has been a steep increase of those patients being referred from acute hospitals to the reablement service. Approximately 20% of patients can be diverted from the community setting to their own homes for rehabilitation.

Through examining the care system, over the period of a year, both reductionist and absorptive approaches were identified. Health and social care professionals migrated from a fragmented approach to supporting patients to develop a structure and processes that provide an integrated service. Recognizing complex and emergent conditions required the capacity and ability of the entire system to absorb unexpected and unplanned patient changes. This led to a focus on demand management, structured communication between different disciplines and shortening discharge times. Overall the length of stay for patients in hospital, requiring in community support after hospital care, reduced from 38 days to an average of 27.5 days.
The absorption of increased levels of complexity in care was achieved through the lowering of professional boundaries, sharing risk and improving ownership of patient discharge. By developing standard operating procedures that aligned across the system (process complexity), agreeing discharge protocols (information complexity), reconfiguring wards (range of illness complexity) and removing territorial boundaries (organisational complexity) participants were able to reduce dysfunctional complexity (including the costs of duplication of resources and long discharge times). Through these changes the capacity to absorb increased levels of patient and service provision complexity was found (see figure 1).

Figure 1: Complexity types and management approaches

Conclusion

After a year of changes in the care system, both reductionist and absorbing approaches to managing complexity were found. For routinized processes standard operating procedures, which already existed, were realigned across the system. This helped to minimize complexity arising from the multiple components which, constitute the treatment route for patients. In contrast, for more complex comorbidity illnesses, often associated with an aging population, an array of factors created uncertainty and unknowns requiring capacity to absorb problems as they emerged. Understanding the characteristics of the complexity within the care system as well as, the consequences of its impact on its operation is an important first step for care professionals and managers. Recognizing the type of complexity proffers the opportunity to develop and select an appropriate response to drive down waste whilst, improving service.

Abstract
The objective of this study was to investigate a complex modular service offering, with a focus on interfaces, from the perspective of the service provider as well as the customer. Case research is conducted in four hospitals, where patients with a complex condition, receive care in a multidisciplinary team. The results show a wide variety of interfaces before, during and after healthcare provision. These interfaces can be categorized based on four purposes: identifying needs & wishes of customers, coordinating services, co-creating services, and increasing transparency of services. We find that interfaces are essential for managing complexity and customization through modularity.

Keywords: Service modularity, Interfaces, Customer involvement
Introduction

Modularity involves building a complex product or service from smaller subsystems that can be designed independently yet function together as a whole (Baldwin & Clark, 2000). Each of these subsystems must be coordinated to fit the overall goal of the complex service. Coordination of services can be achieved by interfaces, as they take care of the interaction between components, modules and providers (Voss & Hsuan, 2009). In health services, coordination is of utmost importance as these services are typically produced by multiple providers and organizations over a long period of time.

For effective treatment of patients with complex conditions, like Down Syndrome (DS), coordination of professionals and care provision is challenging as this context is characterized by complementary and specialized health services. This type of complex care typically consists of professionals from different disciplines, who often represent different organizations (Meijboom, Schmidt-Bakx & Westert, 2011). Moreover, identification of the customer’s needs should be an important part of service provision (Duray et al., 2000). Including the needs and wishes of customers in service provision is necessary to deal with heterogeneous and extensive demands of customers. This indicates that not only professional- and organizational-, but also customer-related challenges complicate the coordination of services in complex care settings. Conceptually, interfaces in service modularity have the potential to alleviate these challenges as they make sure that combined, but independent, modular parts form a functional whole (De Blok et al., 2014; Peters et al., 2018a).

However, the above-mentioned challenges related to interfaces continue to be a rather unexploited perspective (Vähätalo, 2012). Few studies provided evidence on how to manage interfaces, especially the customer ones (Pekkarinen & Ulkuniemi, 2008; De Blok et al., 2014; Peters et al., 2018b). These studies need further elaboration to get a better understanding of interfaces in complex service offerings. We extend the discussion by underlining the role of the customer during modular service provision. The aim of this study is to investigate a complex service offering, with a focus on interfaces, from the perspective of the service provider as well as the customer.

In order to understand interfaces in (healthcare) modularity a literature review was performed. A generic framework was derived from this study in order to describe and analyze complex care provision with specific attention for the dimension of interfaces. Insights from this literature review were used in an exploratory case study on care provision for children with DS. This resulted in a multiple in-depth case study in four hospitals in the Netherlands. The results of this study are discussed and improve our understanding of interfaces in complex modular care provision.

Theoretical background and framework

Modular interfaces have a major role as linkages in the configuration of a complex service offering. They ensure the formation of a functional, coherent whole as they manage the interactions and connections of components when they are combined into the final service offering (Peters et al., 2018a). We use the definition of de Blok et al. (2014) as they developed the most recent and comprehensive healthcare-specific definition of interfaces in service modularity: “the set of rules and guidelines governing the flexible arrangement, interconnections, and interdependence of service components and service providers” (p. 186).

Interfaces

Only few interface classifications can be recognized in the service modularity literature (Peters et al., 2018a). First, de Blok et al. (2014) distinguished four different types of
interfaces: closed-customer (C-C), open-customer (O-C), open-information (O-I) and closed-information (C-I) interfaces. Second, Spring and Santos (2014) distinguish two types of interfaces: structural and procedural interfaces. Last, Broekhuis et al. (2017) make a distinction between functional interfaces and organizational interfaces. We (Peters et al. 2018a) recently argued that these conceptualizations can be aligned. The C-C and O-C interfaces, structural interfaces and functional interfaces focus on the outcome dimension of a service offering and refer to the content part of the service offering, i.e. interactions between components or modules. We described them as customer-flow interfaces that enable patients to flow smoothly through the system, which is necessary to provide continuity of care. Additionally, C-I and O-I interfaces, procedural interfaces and organisational interfaces focus on the process dimension of the service offering and provide linkages between service providers. They refer to the ‘people’ part of the service offering, i.e. interactions between service providers. We describe them as information-flow interfaces that guide the exchange of information and stimulate information transfer about the (changed) patient situation between the different modules involved in the healthcare provision. The flow of information is achieved through collaboration and coordination of activities between service providers (Soffers et al., 2014). However, in service provision, the customer has a more active role (Duray et al., 2000). In order to ensure their active participation, interfaces between providers and customers are needed. This can enable customer involvement before, during and after the service provision.

Customer involvement
Traditionally, customers have been viewed as having a relatively passive role, essentially as recipients of what an organization does for them (Voss et al., 2008). In service provision such as healthcare, the customer could assume a more critical and active role. This means that customers (patients) could be more actively involved by contributing information and knowledge, as they could have an important role in co-creation of a service. However, the service provider could also effectively involve patients in order to get a better understanding of the customer preferences. This requires more active participation during service provision from both the service provider and the customer. In complex service offerings, this is complicated by the substantial diversity in customers’ needs. This is reflected in the various types of providers and organizations involved. Therefore, a better understanding about customer preferences, customer needs, mechanisms of collaboration and coordination, and co-creation is necessary (de Mattos, Fettermann & Cauchick-Miguel, 2019).

The need to better understand the customer perspective in modular services has been pointed out in earlier literature (e.g. Pekkarinen and Ulkuniemi, 2008). However, few studies explicitly focus on modular interfaces, especially interfaces between service provider and customer (Peters et al., 2018a). The way interfaces with customers, i.e. customer need recognition and service co-creation, are handled in a service offering have not received much attention in the previous studies of modularity (Pekkarinen & Ulkuniemi, 2008), despite the attributed importance of customer involvement in modularity (Brax et al., 2017). A few approaches have been identified to discover interfaces with customers (Pekkarinen & Ulkuniemi, 2008; Silander et al., 2017): 1) identification of the customer’s needs, 2) management of relationships with customers and 3) co-creation of services. When service providers engage in these approaches, the role of the customer in the whole service provision becomes (more) visible. This helps the customer to take into account what is required from them during service provision (Duray et al., 2000). Also, it assists service providers in identifying customer preferences and customer needs. Thus, customer involvement in modularized services is a relevant
aspect (Pekkarinen and Ulkuniemi, 2008) that should be possible during the service process (Silander et al., 2017). In sum, interfaces are essential for both service providers and customers in managing complexity and customization through modularity. Therefore, it is essential to truly delve into the customer perspective and form an understanding of the customer’s involvement in modular services.

An implicit assumption in this literature is that the modular service architecture of a service offering needs to be completely specified a priori (Baldwin and Clark, 2000) to understand the functioning of interfaces. Only with such a complete representation of the service offering it is possible to identify coordination and/or communication mechanisms between components and/or service providers. Therefore, we build further on our work presented at the 8th international modularity seminar (Peters et al. 2019). In this study, we applied modular decomposition logic to gain a better understanding of the organization of multidisciplinary Down syndrome healthcare provision. In other words, we created a complete representation of a complex service offering.

**Methodology**

This study aimed to improve the understanding of interfaces by focusing on relationships in the provision of modular care provision for children with DS. A case study research design was chosen since this method is recommended as the most appropriate when, among others, contextual conditions are believed to be highly pertinent to the phenomenon of study (Eisenhardt 1989; Yin, 2003). The case study research was conducted in the field of chronic care provision for children with DS, specifically healthcare provision by multidisciplinary teams in hospitals in the Netherlands. This type of care serves as an example of complex service provision by its wide range of health care professionals/organizations involved and largely heterogeneous patient group. In the Netherlands, pediatric outpatient clinics organize multidisciplinary team appointments for children with DS, including a visit to medical, paramedical, and non-medical specialists, all on the same day (van den Driessen Mareeuw et al., 2017).

Our sample consisted of four multidisciplinary teams (Downteams) from four hospitals in the Netherlands that are geographically dispersed and well-known in the field. To our knowledge, these teams provided a good representation of the overall teams in the Netherlands. By means of purposive sampling we conducted 74 semi-structured interviews with parents of children with DS (N=21), representing the demand-side and members of the multidisciplinary team, representing the supply-side (N=53). Interviews lasted approximately one hour and questions were based on (healthcare) modularity literature. Because the interviewees were not familiar with the vocabulary of modularity, questions were adapted to topics relevant for care provision by Downteams. Moreover, we conducted 12 unstructured observations, 3 at each case, which lasted half a day, during consultations of children with DS. The Ethics Review Board of Tilburg University approved the study. To enable triangulation of information, the data was collected from multiple sources within each hospital: semi-structured interviews, observations and documentation.

The data analysis was conducted during two stages: within-case analysis and cross-case analysis (Barat, Choi & Li, 2011). A thematic analysis of the content was carried out in each stage, using the three steps methodology developed by Miles and Huberman (1994): 1) data reduction, 2) data display, and 3) drawing and verifying conclusions. By making use of this methodology we provided rigor in our research, as we are open to the data and thorough in our data collection. To evaluate the present study, we used the consolidated COREQ criteria list for qualitative research developed by Tong, Sainsbury & Craig (2007). This list made sure that our research adheres to the standard of good
Findings
We present results of the healthcare provision for children with DS by multidisciplinary teams in the Netherlands. We apply modular composition logic and build on previous research in this context (Peters et al., 2018b; Peters et al., 2019).

Within-case analysis
The within-case analysis of interfaces served to identify the interfaces used in each of the separate cases. While describing the interfaces from the four cases, there appeared to be consistency among the cases, so we decided to condense the within-case findings. However, some interfaces were only found in a single case. We found a total of 26 interfaces. We present an illustrative sample of the identified interfaces in Table 1.

Cross-case analysis
From the data presented in the within-case analysis, it appeared that the identified interfaces in each of the cases do not have the same purpose. We therefore re-examined...
the data, looking for similar patterns across the cases by analyzing multiple interface types simultaneously. We revealed four different purposes of the previously identified interfaces. See Table 2 for an overview of these interfaces, their purposes and when they are in play for service provision.

Identification of (heterogeneous) customer requests
Various interfaces (e.g. telephone contact (in advance), information letter) have been identified as interfaces that were aimed at discovering patients’ needs and wishes. For example, the phone call is made a few weeks in advance of the visit to the Downteam. The secretary or specialized nurse asks whether the patient has any specific requests or needs for their visit. Those requests can be medical issues, but also organizational issues like a convenient planning scheme of consultations. For example: “For my last visit to the Downteam, I did not want to visit the ENT-doctor and speech therapist, because I did not need them. The Downteam arranged this and made sure that I had a convenient visit” [Parent]. The healthcare professionals endorsed this expression: “If parents inform us in advance about their requests, either medical or non-medical, we can both use this to our advantage” [Secretary]. By doing this, the Downteams can identify the needs and wishes of their patients and improve their care provision.

Coordinating services
Most interfaces (e.g. multidisciplinary team meeting, referral letter, care coordinator) have been identified as interfaces that enabled coordination and collaboration during care provision. The multidisciplinary team meeting ensures that all professionals come together. In this meeting, all the gathered information of all the professionals involved in one patient is discussed and a follow-up meeting is planned (if necessary). We discovered two separate multidisciplinary meetings with different purposes: the meeting in advance of the patients’ visit is used to adjust care provision based on the medical history of the patient and identification of the patient’s needs. The meeting after the Downteam took place is used to discuss and combine the outcomes of each professional. This ensures that any follow-up treatments are provided in a coherent way and underlines the multidisciplinary nature of the care provision. Remarkably, the care coordinator is only used in one case, but seems to be very important to parents, mainly for non-medical
related questions: “The specialized nurse guides us through the maze of our healthcare system. She is pro-active in her way of working and makes sure our problems are being answered before, after or during our visit to the Downteam” [Parent].

Co-creating services
Only a few interfaces (e.g. patient portal, questionnaire) have been identified as interfaces that were used to co-create services in care provision. The patient portal allows patients to access their personal medical file and makes sure that the patient can pose questions before their visit to the Downteam. To illustrate: “The patient portal gives me the opportunity to look at the medical history of my child and give input for the next visit. But, I feel we could do way more with this added service” [Parent]. This provides healthcare professionals with the possibility to make adjustments to their consultation in a way that matches the requests of the patient. Providing information before their visit allows for co-creation of care provision.

Increasing transparency of services
Several interfaces (e.g. information folders, patient letter) have been identified as interfaces that were used to increase transparency of care provision. The information folder makes sure that patients and parents are acknowledgeable about each healthcare professional that is part of the Downteam. It also makes sure that patients feel more at ease in the hospital, since the folder contains a photograph of each healthcare professional, including pictures of the most important care elements of each professional. To clarify: “…Since we only visit the Downteam once a year, my son has no clue what we will be doing in the hospital. The folder helps us to prepare for the visit, as he sees some pictures of the care elements and a photograph of the doctor. Children with DS are very visual, so this is really of added value…” [Parent].

Discussion
Building on modular theory on interfaces (Peters et al., 2018a) and customer involvement (Pekkarinen & Ulkuniemi, 2008), we have examined whether and how Downteams share information and interact with customers before, during and after care provision. Our empirics showed a wide variety of interfaces. We found that these interfaces served four different purposes. First, we observed interfaces that focus on the identification of (heterogeneous) customer requests. Their purpose is to identify customer preferences and customer needs in order to adjust the service offering. Second, we identified interfaces that focus on coordinating services. Their purpose is to serve as mechanisms that improve the collaboration and coordination in a service offering. Third, we discovered interfaces that focus on the co-creation of services with the customer. Their purpose is to allow for co-creation in a service offering in order to match the needs and wishes of customers. Last, we identified interfaces that focus on enhancing transparency of services. Their purpose is to manage and reduce the complexity in a service offering by increased transparency of the service offering.

In modular service offerings, the role of the customer becomes more important if certain activities are transferred to the customer, e.g. self-service regarding the information about the offerings. In our case, the patients’ understanding of the available treatments and their own medical needs and medical wants becomes essential in care provision. Both literature (Pekkarinen & Ulkuniemi, 2008; Brax et al., 2017; Oertzen et al., 2018) and our empirics show that it is essential to identify and find out the customers’ service needs: the ones that are expressed explicitly but also the needs that are still unconscious/unknown (“under the surface”). Therefore, supporting customer involvement...
in service provision is especially important in the context of healthcare, as the patient is at the center of the core service process regarding treatment, arriving at appointments as scheduled, providing sensitive information about themselves, and following treatment instructions at home. This indicates that the service provider should actively search for those unconscious/unknown customer needs and the patient should actively provide relevant information. Our empirics show that some cases (B, C) are more active in this regard than others (A). The more active cases try to determine customer needs and wants by providing patients and parents with relevant and up-to-date information and knowledge by means of information folders and access to a patient portal. For co-creation to take place, both customer and service provider must be involved, engaged and participating constructively and actively (Oertzen et al., 2018).

Furthermore, we observed a relatively small number of interfaces focusing on the co-creation of service. This could be due to the fact that the complexity of Down syndrome care provision leaves little room for co-creation. Moreover, co-creation of services also depends on the extent to which customers share relevant information and knowledge with their service providers. The active role of customers should not only be reflected during service provision, but they should also, (pro) actively share information between involved service providers. However, there appeared to be a contradiction in our empirics. On the one hand customers were expected to participate in information transfer, while at the same time some of them were criticized of interfering with care provision too much. In this study, the minor role of customer involvement in the co-creation of services may be linked to the steep information asymmetry between healthcare professional and the patient, an essential characteristic of hospital services (Berry & Bendapudi, 2007). Also, in the context of co-creation of services that operate in increasingly networked environments (e.g. construction services, health services), it becomes harder to develop interfaces a-priori due to the involvement of various stakeholders (Alexander, Jaakkola & Hollebeek, 2018; Peters et al., 2018a).

**Conclusion**

We address the call to conduct studies with interfaces as the central unit of analysis, instead of interfaces being just one theme among many (Voss & Hsuan, 2009). In our study, we explore how interfaces manifest themselves in a multi-provider context (Vähätalo, 2012), with special reference to customer involvement. We build on the proposition posed by Peters et al. (2018a) who argue that interfaces in complex modular services improve coordination of decomposed tasks within service provision not only across professional boundaries, but also organisational boundaries (p. 6604). Our cases indicate that modular interfaces help customers to better manage a comprehensive and complex service in its entirety. It is in this sense that interfaces improve coordination of tasks and information across professional boundaries, organisational boundaries.

Furthermore, few studies provided evidence on how to manage interfaces, especially the customer ones (Pekkarinen & Ulkuniemi, 2008; De Blok et al., 2014). These studies need further elaboration to get a better understanding of interfaces in complex service offerings. We build on existing work in this field, but we differ from de Blok et al. (2014) because we underline the role of the customer before, during and after service provision. The interfaces found by de Blok et al. (2014) make sure that the catalogue of a service provider becomes more explicit, i.e. how to connect the available care and service components, whereas our study adds new sections to the catalogue, i.e. what does the customer need and how can we (re)arrange care and service components. It is in this sense that interfaces can provide more added value during service specification (de Blok et al., 2010).
From a managerial perspective, practitioners can find our interface purposes very helpful. These purposes provide a starting point for other healthcare professionals to identify interfaces in their own situation. In this way, interfaces can be made visible, for example in modular service architectures, in the same way modules and components can be visualized. This allows care providers to not only focus on care provision itself, but also make explicit how the various parts of a modular service are connected. It gives insights in the interfaces being used, but also the one not being used. If a care provider observes that there are hardly any interfaces that focus on identifying customer requests or co-creation of services, it might be that his patients are not being heard.

Conclusion
The findings of our multiple in-depth case study increase our knowledge on modular interfaces (with customers) within a service offering in the context of a complex hospital modular care setting. We discovered a wide variety of interfaces and found that these interfaces can be categorized based on four purposes: identifying needs & wishes of customers, coordinating services, co-creating services, and increasing transparency of services. They are essential for both service providers and customers in managing complexity and customization through modularity. With respect to managing complexity, our study showed that as the tasks and care elements included in, and related to, the service are made more visible, the role of the customer in the whole service process also becomes more visible. This helps the customer to take into account what is required from them during the service, which increases awareness of the complex service offering. With respect to customization, our study showed that identifying customer preferences and customer needs is essential in order to co-create services. This helps the service provider to take into account what is necessary to deliver a customized service offering.

Abstract

This paper reports on an empirical study evaluating the use of visual tools in an NHS Clinical Commissioning Group, City CCG. UK CCGs commission most of the community and hospital health care services, these are wide ranging and include emergency care, community health services, and rehabilitative care. Consequently, the need to communicate and design complex systems with staff and service users is common. This paper specifically focuses on how visual tools impacted on this challenging process - to communicate and co-produce complex operational systems. It finds the approach used widened participation and facilitated depth of conceptualisation of the underlying systems.

Keywords: Visual, healthcare, co-production

Introduction

The use of visual tools is well established in Operations Management (Tezel, Koskela, and Tzortzopoulos, 2016), general management (Meyer, Höllerer, Jancsary and van Leeuwen 2013), strategic decision making (Paroutis, Franco, and Papadopoulos, 2015) and healthcare (IHI 2018). This paper seeks to extend and explore the type of visual tools used in healthcare beyond status boards and dashboards (IHI 2019 and Jeffs, Beswick,, Lo, Lai, Chhun, and Campbell, 2014.), to engage with aspects of co-production of operational designs. This is significant because the multi-stakeholder environment in which most healthcare settings operate are such that they need to engage with clinical staff, managerial staff, social care, patients and their families.
The subject organisation City CCG had been using visual communication to engage staff and service users in the co-production of the services they commission for a number of years, specifically using the tool graphicing. In graphicing, complex messages are streamlined into visual images that perform a similar function to process diagrams such as value stream maps (Rother and Shook 2003) but with a more accessible presentation for healthcare. The general perception across the CCG was that the graphicing method was a useful tool that allowed staff and service users to gain a more informed and holistic understanding of services. This research seeks to explore the extent to which the graphicing approach supports the co-production of operational system designs. In order to provide a robust evidence based on which the CCG could base decisions for the use of the graphicing method, the empirical study set out to evaluate the efficacy of the graphicing method by asking the following research questions:

1. How are the graphicing images produced and used?
2. How are the graphicing images perceived by stakeholders?

Methods

To answer the research questions the project focused on the use of images produced through graphicing in two commissioning areas: the system of care provided for frail older patients and the redesign of patient pathways in the renal, cardiology and respiratory service area (Figure 1 and 2). In both cases the images had been co-produced using a range of engagement activities and were drawn by the Head of Engagement and Communication using tailored software.

A qualitative approach to exploring the use of graphicing in these areas was chosen in order to gain an in-depth understanding of its use. This involved the use of both participant observation and semi-structured interviews.

The researchers attended a range of engagement workshops to observe the co-produced nature of the images and their use in practice, and carried out 26 semi-structured interviews with key stakeholders, including: healthcare professionals such as consultants, nurses, and pharmacists; managerial staff; and admin staff. Some interviews were with individuals and others were in small groups. This was format directed by the way people arrived for the workshops - either as individuals or in groups.
The interview recordings were transcribed and coded using thematic analysis (Braun and Clarke 2006). The question style followed the SHOWeD framework advocated in the photovoice method (Wang 1999). SHOWeD aims to facilitate in depth talk about images and recommends questions such as What do you See here? What is really Happening? How does this relate to Our lives? Why does this problem or strength really exist? What
can we Do about it? While these questions were originally designed for use in participatory action research in order to facilitate bottom up social change, they also worked well in this setting whereby the focus was stakeholder inclusion in pathway redesign. The project was granted ethical approval from the University of Leicester and written consent was obtained from all involved.

The interview transcripts were analysed using thematic analysis; this iterative process that identifies patterns of meaning across the data. The themes that emerge are closely related to the data, allowing an in-depth focus on the data corpus (Guest et al 2012). Braun and Clarke’s (2006) adaptable six-step guide was used in order to thematically analyse the interviews. This involved: familiarisation with the data; coding; the identification of themes within, between and across codes; review of the themes; formalisation of the themes; and write up. In accordance with Braun and Clarke (2006) data was initially organised into 29 codes using Nvivo 12 Pro. A preliminary coding framework based on the interview guide was refined iteratively between both researchers. An open approach to coding allowed additional code identification and all revisions to the coding framework were applied to the transcripts that had been previously coded.

Results

From the coding process four themes emerged from the 29 codes, these are: co-creation facilitation; facilitated insight; data density; and design. Each of the themes are illustrated and discussed in the sections that follow, focusing particularly on stakeholder perception. Generally the images were overwhelmingly well received and with participants broadly supportive of their use:

P2: I quite like the simple way that the pathway is shown on there, and it is quite easy to understand. It’s not just data so that helps.

P21: Yes, it’s basic but straightforward and easy to understand, so you can take it in pretty quickly, so it’s quite a good point of view and understand very quickly.

P3: There is nothing more powerful than displaying in a visual format. It seems to flow a lot better for people that aren’t clinically minded or have that background, but in layman’s terms it’s very easy to understand.

Co-creation facilitation: This theme relates to the extent to which graphicing facilitates the range of stakeholders in producing the graphing images. This theme has two aspects, capacity for shared understanding and then this enables participation in the adaption of the image. This stage - that of understanding is a logical precursor to participants feeling they can participate in adapting the images. This first stage of understanding is illustrated by:

P20: So, for me, as much as anything it’s really helped me to get to understand the patient journey through all of these specialities….it’s helped me personally get a better understanding of all of the pathways.

P6-9: It’s self explanatory and I think it would be quite easy for anybody to look at it and understand it at whatever level. … That on a board in a staff room really is a good
way of communicating and sending out a message, and so people can see oh that’s going to happen, and that’s going to happen.

In terms of participating in the development of the graphicing image and design of the underlying system, participants commented:

**P15:** What was helpful was that when we discussed it with other people at the LIA event, obviously getting their perceptions in terms of things that needed adding in, because you have one very narrow perspective of a service in terms of a pathway that you directly deal with, but other people have other experiences that need adding in as well.

**P20:** So this is probably at least the second or third, if not fourth iteration of how they actually started and then we’ve used them in consultation process, and also in design workshops so these pathways show us what the journey of the patient is now, and we’ve been able to scribble on them and actually get different key people involved to actually say how we want the pathway to look in the future.

**P16:** I think it’s just been a team effort and getting lots of different people’s opinions on how they think things flow through the Department, and the best way of doing that, it has given quite a lot of insight into how different the team work and trying to bring that together.

These quotes demonstrate the iterative (P20) and team based approach (P15 and P16) enabled by graphicing. They highlight the benefits of having several viewpoints (P15) in developing the design of the underlying system. The iterative approach allows nuance to be added to develop both the design and the image that conveys the system design (P16).

**Facilitated insight:** This theme addresses the potential of the visual image to allow the viewer an additional insight or understanding of the system they are viewing. This was particularly prominent in participants who were involved in the production of the more abstract frailty image (Figure 1):

**P22** I think it’s useful to have complexity on the page, so people can instantly see that looks a bit ridiculous, what can we do to improve it, but she’s taken ... it actually this heart failure one and improved this, because the flow is not necessarily right, where these things land on the page, is probably because you can fit them there, but as I say, the referral routes, the GP, the patient at home and this self-report, HF, probably all could happen at the same point, so they’re aligned.

**P4:** And, actually what you find is, your own thinking is enriched and developed by talking that way because you’re getting around that ‘camp fire’ if you like, of a basic image or a metaphor...... it’s been really helpful for me to help me conceptualise how we bring about change and the further change within this system in the future... as a commissioner, it helps you to think about the whole board. So chess players talk about seeing the whole board and I think this helps you, from a strategic point of view, to say, “This is a system within a system.”
So it helps people to think a bit more creatively about how we can use that resource, rather than saying, “This is health, this is social care.” Do you know what I mean? It’s almost impossible to completely separate the two and we certainly do debate whether something is health or social care on a daily basis. But actually if we’re doing this integration right and we are truly person-centred, some of that is irrelevant.

The respondents here highlight the advantage of having the system shown visually (P4). This allows the viewers to see excessive complexity of the system or to see the ‘whole picture’ (P22). It also overcomes artificial barriers in the care system created by having separate systems for health and social care (P1).

Data density: This highlights the participants’ ongoing negotiation between detail and simplicity. Overall, the participants welcomed the accessibility of the images but often found it challenging to decide what information to include and exclude.

So it’s a difficult balance, I think, between overcomplicating the image and putting lots of words on there, because I think then it would lose its impact of the actual image itself.

Yes, you might be able to come up with something that’s a bit more condensed there, you absolutely don’t want to make it too complicated.

I think pathways can get a bit over-complicated. So this one is bordering on getting over-complicated and some of them get much more complicated than that, but it is useful for specific conditions.

So you can overcompensate and make it a too cluttered image and at the same time you want to give enough information there that you’re not answering 50 questions about why ‘x, w and z’ isn’t in there. So it’s a bit of a delicate balance between too cluttered, on one hand, and not enough information on the other.

From these comments the respondents (e.g. P23) are acknowledging the need to balance the complexity of the image – thus reflecting the design of the underlying system - with the need to be comprehensible to the viewer (P4).

Design: The final theme of design is united by participants’ comments on specific aspects of the design of graphic images, for example use of colour or icons. We specifically asked about flow and use of colour but comments on the icons and how they did or did not represent different groups emerged from the data.

I think the way the arrows go from left to right and it’s quite simple. I think sometimes when you get something in the middle of a big piece of paper and all the arrows go off, and it just looks like a bit of spaghetti, it’s a bit hard to understand sometimes and it takes a lot of energy to try and get your head round it. And instantly I could see the things that I would think, ‘Oh! I might want to just tweak that a little bit.’

So I think seeing it with the images and looking at the flow, it makes you question, it makes you stop and it makes you have a look at the individual processes and pathways
and making sure that there is nothing missing. So it does make it a lot easier to see that particular pathway and the processes.

P2 comments that the design of having the flow from left to right helps understanding and thus design “I would instantly see….I might want to just tweak that a little bit”. P3 states the flow helps the viewer understand the detailed processes and make sure nothing is missing.

The representation of specific roles by images of people was problematic; respondents reported a tension between who actually filled the roles and how they were represented on the images. As P2 states:

P2: ... we’ve got some female faces, which is good, but it’s a little bit stereotypical isn’t it?

The use of icons of people, participants commented, made the images more accessible, to ‘humanise’ the service. Participants said things like:

P3: just putting pictures of people on it just makes it feel a little bit more real, doesn’t it?

Interviewer: What aspects of the visuals have people liked?

P19: The use of characters. I think the great thing about it is that it sort of humanises the process in a way.

The use of colour was also commented upon:

P1: Possibly some use of different colours, like the arrows all being the same colour, whether that would break it up a bit. Not so much on the Rapid Access one but on the AF Referrals, there’s a lot going on at the end there and it might just make that a bit clearer.

P6-9: The thing that is slightly bothering me is that heart failure is different, it’s not done as a flow in blue, it’s ....I think I prefer the blue to the black lines though....

P3: Good colour coordination and it displays the message which you are trying to portray really.

The respondents did not have single clear view on how colour should be used - some liked the use of colour P3, but the focus group with respondents P6-9 had some issues with how colour was used.

Discussion

The four themes clearly overlap and each have differing levels of support in the evidence. Co-creation facilitation had the most substantial body of evidence, with the speed and accessibility frequently cited as broadening the number of people who were prepared to engage with the images and also how quickly they were able to assimilate the message. For the images relating to renal cardiology and respiratory care there were several design
iterations and many comments from participants written on the images that were later incorporated. This indicates that the participants felt they were empowered to change the designs – indicating a lower level of perceived finishedness (Bresciani et al. 2008). This ability to sanction viewers to modify the image with their own insights is key part of the co-design part of co-creation.

In terms of the next theme, facilitated insight, the first stage of co-creation facilitation - that of quick and easy understanding of the images - also supports facilitated insight. However, facilitated insight goes beyond understanding and allows viewers to gain insight into the underlying system that they might not have been able to obtain via other mediums. Bresciani et al. (2008) outline the related ideas of inference support, discourse management and directed focus and these constructs support this theme of facilitated insight. Inference support and directed focus allow viewers of the images to make connections between data to come to useful conclusions. Discourse management allows groups to have productive discussions, this is particularly useful in group decision making environment. This ability, to provide an in depth overview, is documented by Meyer, et al.(2013 p 493) who state “visual representation can objectify social arrangements and socially constructed realities through the absence of predication, explicit logical conjunction, and grammatical mood, and through its capacity for accurate and detailed depiction.”

The data density theme reflects a tension between including detail and simplicity of the message. In the field of graphic design and use of data Tufte (2001) states that “data rich designs give a context and credibility” and extorts to “maximise data density and the size of data matrix within reason”. This is balanced by McCandless (2014) who highlights the need for story should be combined, but not overwhelmed, with information, function and visual form. He suggests that these aspects should be carefully combined for a successful visualisation and data without a story is dull; if the visual has no function it is “useless” and deficiency in visual form renders the image lacking structure and harmony.

The design theme pulls together a wide range of comments regarding the design of the images and the underlying system. The results have suggested a number of recommendations for designers of graphing visuals:

1. The use of icons – develop a neutral set of appealing icons
2. Standardisation – including colour and icons
3. Management of data density to balance detail and accessibility
4. Consideration of flow in terms of both representation and underlying system design.

The development of this approach could support the future facilitation of graphing images and co-production of images. It could also lay the foundations for its more systemic use in other CCGs.

In terms of the role of these visual tools, they echo the role of value stream mapping (Rother and Shook, 2003) in non-healthcare applications but emphasising the role of human actors in the system design. As such they develop the use of visual tools in healthcare from daily operations management in the form of dashboards to the design of the underlying system of operations also known as the operating model (Bateman 2018).
Conclusions
Consistently the participants liked the images and found them accessible - this enhanced the number of people prepared to engage with them. In addition the findings showed that the use of visual tools greatly increased understanding and accessibility of the two projects observed, both in terms of the number of people who understood the design of the projects and also their depth of understanding. In terms of the two research questions:

1. How are the graphicing images produced and used?
2. How are the graphicing images perceived by stakeholders?

The graphicing images are produced by an iterative process of co-production involving a wide range of stakeholders. The images are positively perceived by the stakeholders both in terms of liking the images, but also valuing their underlying utility in terms of system design.

The co-production of the system design was improved by the wide level of consultation and this was facilitated by the use of visual tools. The graphicing method also aided the reconceptualization of the underlying systems and processes for those people with detailed knowledge of the systems.

This approach represents an extension to the type of visual tools used in healthcare from day to day operations management extensively used in status boards and dashboards to a strategic approach that addresses operations system design. This approach was particularly useful for spanning the artificial boundaries between health and social care. In terms of the type of visual research conducted here it addresses the area of “practice” as defined by Meyer et al. (2013) and has the characteristics typified by the category of research e.g. examining visuals that are socially meaningful and produced by the field actors. With the focus of the research on the use and development of the visual artefacts.

In summary the use of graphicing had a marked positive impact on stakeholder understanding, involvement and engagement and significantly allowed a step change in the ability to design healthcare systems. This reflects the need to develop Operations Management approaches that take greater account of the context (Radnor, Holweg, and Waring .2012) - in this case a more human centred, public service environment.

Abstract
Healthcare organisations continue to invest in process redesign as a way to improve quality using continuous improvement and Lean approaches. An Interrupted Time Series (ITS) evaluated the outcomes of a Rapid Process Improvement Workshop (RPIW) at a National Health Service (NHS) mental health hospital Trust. The ITS analysis was unable to confirm that the RPIW was successful. The limitations of conducting an ITS using routinely collected data needs to be recognised. It is important to appreciate the social and cultural context in which the intervention is embedded to effectively evaluate improvements, which implies the need for a mixed-methods approach.

Keywords: Healthcare, Process Improvement, Rapid Process Improvement Workshops (RPIWs), Evaluation

Introduction
Healthcare systems face many challenges, such as population aging, rising costs (OECD, 2017), inflation, and cost of new technologies (Silander et al., 2017). In response healthcare organisations throughout the world continue to make large investments in process redesign with the goal of treating patients more effectively without incurring additional costs (Berwick et al., 2008). Process redesign aims to reduce variation, delays, errors and eliminate redundant processes (Locock, 2003). Healthcare indicators are often used to assess the operational effectiveness of healthcare systems (OECD, 2017). The use of metrics may help healthcare systems become more efficient and effective whilst improving the quality of care (Boaden et al., 2008).

At the level of the process, however, there is a need to understand the link between process improvement, human resource management and how these impact on outcomes and the quality of patient care offered (Leggat et al., 2015). It is important, therefore, to evaluate process improvements in healthcare. Evaluating the outcomes to see if process improvements are achieved is an important area of research for two reasons. Firstly, it is important to evaluate: i) the intervention process, so that it can be improved; and ii) the change in performance achieved by the intervention, which can be measured using healthcare indicators (metrics). This paper evaluates the use of a Rapid Process
Improvement Workshop (RPIW) applied at a National Health Service (NHS) Hospital Trust in the North East of England UK, which aimed to improve the referral process on a psychosis care pathway.

**Literature Review**
Continuous improvement and Lean aim to improve the effectiveness and efficiency of healthcare delivery (Brandao de Souza, 2009). Understanding what is meant by ‘Lean’ can be difficult as the term ‘Lean’ has been used as a label to describe the majority of process improvements initiatives in healthcare (Matthias and Brown, 2016). The approach adopted is often similar to the Master Class (Pullin, 1998; Bateman and SMMT Industry Forum, 2001) that seeks to provide a structured approach to process improvement. Rapid Improvement Events (RIE) (e.g., Papadopoulos *et al.*, 2011), Rapid Process Improvement Workshops (RPIWs) (Plsek, 2014) and Kaizen Events (Glover *et al.*, 2014) are examples of such structured improvement programmes. These events/workshops have been used in healthcare for achieving process improvement in targeted areas but are not Lean in its truest form. Whilst these criticisms may be acknowledged, RPIWs and RIEs are still a popular method of bringing about process improvement, therefore, understanding if these events ‘work’ is of interest to both the academic and practitioner communities.

**The North East Transformation System (NETS)**
In the North East of England, the NHS North East (NHS NE) performs well in terms of meeting governmental targets and achieving performance measures (NHS North East., 2008). The population of the region, however, has poor health possibly resulting from the industrial heritage of the area and other socio-economic factors (NHS North East., 2008). This presents a paradox in terms of a good healthcare system (employing 77,000 staff) but poor health of the population of the region (2.4 million people). Graham (2009) commented that this paradox could result from factors that lie outside of the healthcare system. Marmot *et al.’s* (2010) work addressed this by demonstrating that social and economic circumstances, how people choose to live and work impacts upon their health. NHS NE, however, believed the healthcare system could perform much better by adopting a system wide approach to change that focused on quality and safety (Erskine *et al.*, 2009). Up until that point, the implementation of quality improvement methods in the NHS NE had involved relatively small-scale interventions confined to particular hospital departments and support services (Fillingham, 2007).

The North East Transformation System (NETS) was launched in 2007 and was a unique experiment in the adoption of transformational change in a complex system, namely the NHS in North East England (NHS North East., 2008). NHS North East received support from the Virginia Mason Medical Center in Seattle, which developed the Virginia Mason Production System (https://www.virginiamason.org/VMPS). This was derived from the Toyota Production System (TPS). The NETS comprised an ambitious regional vision ‘to put the patient at the heart of everything we do’, a ‘compact’ (a psychological contract between staff and the organisation which specified mutual expectations) and the ‘method’ (the VMPS) which adopted Rapid Process Improvement Workshops (RPIWs) (Erskine *et al.*, 2009).

*Rapid Process Improvement Workshops (RPIWs)*
A Rapid Process Improvement Workshop (RPIW) could be described using Locock’s (2003) terminology of healthcare “redesign”. Locock (2003) described redesign as looking at the best process from the bottom up as a complete redesign to achieve quick
and efficient care; the removal of all delays and additional steps; and identifying and eradicating where errors can occur. Rapid Process Improvement Workshops (RPIWs) adopted Lean problem solving tools, value stream mapping, 5S, visual control; Kanban; streamlining flow; and standard operations (Bohmer and Ferlins, 2006). The team members involved in a 5-day RPIW are set out below in Table 1.

</table>

Each RPIW had a mid-week and final report-out where all RPIW team members jointly presented progress and the outcome of the intervention. These were based upon a framework that included: an overview – team members, current situation, process flow, TAKT time (Miltonburg, 2001), targets and boundaries; an analysis of standard work; a progress report that measured prior performance and targets (for space, inventory, staff walking distance, parts travel distance, lead-time, quality, productivity, 5S and set-up reduction). The report-outs included a value stream map, TAKT time calculations and work flow diagrams that showed the status before and after the intervention as well as through 30, 60 and 90 day follow-ups (which formed part of the RPIW process).

Evaluating Process Improvement Events
Chavez et al. (2013) argued that the Lean literature is biased in terms of the effectiveness of Lean that is reported, as well as the improvement in measured metrics that are an outcome of the intervention. Dickson et al. (2009, p. 508) elaborated that there is a reporting bias because organisations that fail to meet their objectives, or do not achieve the intended outcomes, are unlikely to report the interventions or the reasons for failure. Young and McClean (2009, p. 384) commented that the evidence whether “Lean can systematically and dramatically improve a sector as significant as healthcare is still a matter of belief, rather than proof”. Leggat et al. (2015, p. 161) conducted a systematic review and commented “while the academic literature contains a large and growing number of papers that suggest positive outcomes of process redesign in hospitals, reviews of the impact of process redesign are largely inconclusive with unsatisfactory methodologies limiting conclusions”.

3
This study attempts to address these concerns by adopting an Interrupted Time Series (ITS) analysis. An ITS could be described as quasi-experimental in design, and can provide greater internal validity in terms of the hierarchy of evidence (Hansen, 2014). The ITS was used to evaluate the outcomes of a Rapid Process Improvement Workshop as a method to improve the quality of care on a psychosis care pathway. This study seeks to address if RPIWs can be an effective way to enact process improvement and increase quality of care of patients?

**Methodology**

A National Health Service (NHS) mental health Trust psychosis pathway was the unit of analysis that comprised three sequential processes: referral, assessment and discharge. This paper focuses on the referral process of the pathway specifically. The RPIW was conducted at three intervention sites. The training was conducted off-site at a training centre and was attended by 43 individuals from the three sites including Trust employees, carers and family members and supported by the Certified Workshop Leaders and the Trusts Kaizen Promotion Office (KPO). The RPIW was set up to address a range of problems identified on the psychosis pathway including:

- No standard approach to developing a care plan;
- No standard approach to involving other disciplines;
- No standard assessment pathway and lack of clarity when assessment stops and treatment starts;
- No standard information sent to service users/carers;
- Time taken to input patient treatment assessment data on the information system was variable.

The aims and targets set out by the sponsor on day 1 of the RPIW were:

- To effect a complete redesign of the patient pathway;
- To address patient needs and the needs of carers;
- To demonstrate quality of service and value for money;
- To reduce waiting times for the ‘customers’ (patients, carers, GPs, family members);
- To increase face-to-face contact time by 50%.

A primary objective of the RPIW was to increase the proportion of the referrals assessed on the same day and to reduce the time taken from referral-to-assessment for those not assessed on the same day. By referring and starting a patient’s treatment quicker, it was believed would increase the quality of care offered. The hypotheses, used to measure the RPIW, therefore, can be stated as:

- The number of patients assessed on the day-of-referral would increase;
- The time from referral-to-assessment would decrease.

**Data Collection and analysis**

Data were extracted from the Trust’s electronic patient record system covering a two and a half year period that included one-year pre-RPIW and 18 months post RPIW. The design included three intervention sites (localities within the Trust) with five control localities. A multiple Interrupted Time Series (ITS) analysis was used to analyse the
data as multiple observations were available pre- and post-intervention. A random effects logistic regression model was adopted because the dependent variable (the number of patients assessed on the day-of-referral) is a Boolean variable (i.e., has one of two values only). The random effects negative binomial regression model was appropriate given the count nature of the variable time from referral-to-assessment (Winkelmann, 1995). In both cases, the clustering was on the site.

**Results**

The descriptive statistics associated with the intervention, controls and frequency of patients treated are set out in Table 2 below.

</tbody>
</table>

The time from referral received to first allocation was highly skewed with a mean 4.1 days and the standard deviation was 10.3 days as demonstrated in Figure 1.

![Figure 1- Time in days to first allocation from receipt of referral](image)

For most patients, 59% (95% CI: 56%, 61%), the date of first allocation was the same as the date that the referral was received. Initial exploration suggested that the most appropriate way to model the data was to fit a zero inflated negative binomial regression model. Using this procedure the likelihood of being allocated on the date that the
referral is received and the length of time spent waiting for other patients (that is those for whom the date of allocation was not the same as the date of referral) are modelled simultaneously. Summary data corresponding to these variables are plotted by calendar month in Figures 2 and 3.

**Figure 2 – Proportion of patients allocated on the day that the referral was received**

**Figure 3 – Mean time to allocation for those patients who did not receive an allocation on the day that the referral was received**
Any effect of the RPIW would appear to be in hypothesised direction. There appears to be a higher proportion of patients allocated the day that the referral was received in intervention sites following the RPIW and the mean time to allocation for the remaining patients appears to be lower than in control sites following the intervention. The hypothesis that the number of patients assessed on the day-of-referral would increase due to the RPIW intervention was not supported. The time from referral-to-assessment was reduced at both the intervention and control sites.

The hypothesis that the time from referral-to-assessment would reduce due to the intervention was also not supported. Time to allocation fell more in control sites but this can primarily be attributed to the fact that time to allocation has already fallen considerably in intervention sites six months prior to the intervention. There was much less room for improvement in intervention sites which may explain the modest reduction in time to allocation observed in those sites. It is very difficult to explain the very large reduction observed in control sites.

Discussion
A rigorous multiple interrupted design has been used to evaluate process improvement in healthcare. The ITS analysis concluded that the impact of this RPIW was not statistically significant on the duration from referral to first assessment and the duration from referral to diagnostic formulation for patients (in terms of either the number of patients assessed on the day-of-referral, or the time taken between referral and assessment for those not treated on the day-of-referral). The evidence demonstrated that there was a step change in the time to assessment at both the intervention and control sites, particularly after the process improvement. If the research failed to include the controls, the evaluation would have indicated improvements at the intervention sites. These outcomes would have been supported by the previous literature in terms of reporting positive process improvement outcomes.

It is somewhat coincidental that there were improvements at both the intervention and control sites after the process improvements were implemented. There is unfortunately no data to understand why. This puts into conflict the advocates of evidence-based decision making who propose decision makers should adopt approaches that scientific inquiry has evaluated as more effective (McDaniel Jr and Lanham, 2009). It is possible that the improvements were a result of a number of factors that the ITS could not detect. One consideration could be the sampling selection of the intervention and control sites themselves being within the same hospital Trust and geographical region. This highlights a limitation of the sampling approach and the ITS method in general. For example, the ITS drew on routinely collected data in order to adopt a standardised experimental design.

It is argued that process improvement interventions can only be successfully evaluated if the content, context, and application are clearly understood (Walshe, 2007; Boaden et al., 2008). In this case study, the ITS analysis only addressed one of the five objectives that the RPIW set out to accomplish: to reduce waiting times for the patients, carers, GPs, family members. The ITS was not a suitable method for measuring whether the RPIW achieved the other four objectives (to affect a complete redesign of the patient pathway; to address patient needs and the needs of carers; to demonstrate quality of service and value for money; to increase face-to-face contact time by 50%) which were qualitative in nature and required different research methods to measure the impact. For example, a number of positive changes were directly attributable to having standardised processes supported by common documentation (see Hunter et al., 2014). Acceptance of standard work had highlighted gaps in the structures of the multi-disciplinary teams in different locations, but had also empowered staff to make requests for – and obtain – team members.
with the professional skills to fill those gaps. From a human resource management perspective, psychosis team care co-ordinators were now better equipped to deal with their workload and staff sickness absenteeism had reduced. This supports the argument set out by Leggat et al. (2015) from their systematic review of process redesign methods in hospitals. It was identified that there needs to be more focus on the linkages between process redesign, the people involved and how this combines to improve patient care (Leggat et al., 2015).

These inconclusive results suggest that it is important to do further research to evaluate process improvement interventions in a range of healthcare contexts. As Øvretveit and Gustafson (2002) argued, that just looking at the measured outcomes of any intervention does not mean there has not been improvement in process or the process improvement approach is not suitable. An ITS analysis reports on outcomes not process. Qualitative research methodologies would be appropriate for evaluating context, content and application elements of an intervention (Walshe, 2007), where the objective is to generate hypotheses. This might sit uncomfortably with advocates of evidence-based decision making who argue that decision makers and managers should only adopt practices that scientific inquiry has demonstrated to be effective (McDaniel Jr and Lanham, 2009). Quasi-experimental designs such as multiple interrupted time series rate highly on the hierarchies of evidence and are appropriate for establishing causality (Barends et al., 2014), but may be limited in interpreting a number of outcomes resulting from process improvement interventions. Research should adopt a pragmatic approach (qualitative, quantitative, or both) to healthcare process improvement interventions.

**Conclusion**

Healthcare organisations are continuing to support process redesigns in order to treat patients more effectively. Process improvements that utilise a structured approach are frequently reported in the literature. Evaluating if the outcomes of structured process improvement events are achieved is an important area of research. The North East Transformation system adopted the Virginia Mason Production System (VMPS) which utilises Rapid Process Improvement Workshops (RPIWs) as a structured approach to bring about process improvements. This paper evaluated an RPIW conducted on a psychosis pathway that was part of a NHS mental health Trust. The evaluation concentrated on the referral process of the pathway specifically.

The ITS analysis concluded that the impact of this RPIW was not statistically significant on the duration from referral to first assessment and the duration from referral to diagnostic formulation for patients. This would imply that RPIWs are not a successful mechanism for implementing process improvements in healthcare. The limitations of conducting an ITS using routinely collected data, however, needs to be recognised. What is required is an appreciation of the social and cultural context in which the intervention is embedded.

The research had a number of limitations. The geographical proximity of the control and intervention sites could have led to interactions that undermined the internal validity of the quasi-experimental design. Further work could consider intervention and control sites in locations where interactions are minimised. The ITS analysis drew upon routinely collected data which limited the performance criteria that could be assessed. It is important to understand the metrics and healthcare indicators identified, and their limitations when evaluating process improvements.

Abstract
This paper aims to evaluate how healthcare providers make use of unsolicited and real-time patient feedback, posted on online website called Care Opinion (CO), to improve the delivery of care and thereby embrace the characteristics of highly reliable organisations (HRO). The five characteristics of HRO – pre-occupation with failure, reluctance to simplify, sensitivity to operations, commitment to resilience, and deference to expertise, is tested in the selected English NHS Trust that has Care Opinion subscription. Semi-structured interviews with CO and NHS employees revealed that staff reaction and response to online patient stories is faster and positively influences NHS service delivery processes.

Keywords: Healthcare, Highly Reliable Organisations, Patient Feedback

Introduction
W. Edwards Deming the Quality guru stated, “Quality is everyone’s responsibility and we never have to stop getting better” and the statement beautifully equates to the context of healthcare and patient safety. Despite of two decades of efforts to make healthcare safer and highly reliable the search for perfection continues with a big gap to be filled (Woods-Hill and Bird, 2019; Babyar, 2019). The key issue for studies of safer healthcare systems is therefore the understanding of how social and technical systems combine to generate a reliable healthcare organisation with just culture that promote staff pre-reporting and encourage learning (Weick and Sutcliffe, 2007).

The principles of highly reliable organizations (HRO) focuses on developing organization’s ability to pre-empt failure, deliver and sustain almost error-free performance over long time period, resulting in improved patient safety and creating a culture and environment that promotes safety (Weick and Sutcliffe, 2007; Chassin and Loeb, 2013). The principles of HRO has been successfully implemented in the Air Traffic control system, nuclear power stations, Navy nuclear aircrafts, parks and other industries. Researchers have argued that every organization need to identify and
In an era where usage of social media has become a cultural norm in the western countries, healthcare organisations can benefit a lot from usage of such data to transform their organisational culture from provider-focused to patient-centred (Rozenblum et al., 2017). The application of HRO principles in providing error-free healthcare services can be realized by going beyond accessing the patient feedback through the hospital system to learning from experiential feedback provided by patients and/or their relatives on social media and other feedback websites. Asking patients to share their experience of care received at the hospitals is realized to be a widespread way of generating useful knowledge for improving service delivery (Ziewitz, 2017; Sheard et al. 2017). The readily available crowdsourcing data from social media platform or dedicated patient stories webpages are being used by proactive hospitals to conduct problem-solving, quality control, and organizational learning (Adams, 2011; Rozenblum et al. 2017). Care Opinion (CO) is one of the online websites that provides a platform for patients to share their experiences of care which helps the other patients and the NHS to receive and deliver good quality of care.

The aim of this paper is to evaluate how healthcare providers make use of unsolicited and real-time patient feedback to learn and improve their service delivery process by engaging with patient stories posted on a social media platform called ‘Care Opinion’. In an attempt to understand the relationship between using experiential feedback and exhibiting HRO characteristics (see table 1), authors apply the five characteristics of HRO (Weick and Sutcliffe, 2007; Hopkins, 2007) – pre-occupation with failure, reluctance to simplify, sensitivity to operations, commitment to resilience, and deference to expertise, to analyse how a selected NHS Trust in England make changes in their processes and practices to have a holistic approach towards patient-centred care. Semi-structured interviews with Care Opinion and the selected NHS Trust revealed the greater benefits of integrating social media feedback with traditional methods used in hospital for collection of patient feedback. The unsolicited real-time feedback results in quick response and action in majority of the cases and it has helped to improve the accountability and empowerment to conduct improvement at the source – one of the key principles of HRO, i.e. deference to expertise.

Literature review

HRO and its characteristics

Adverse events and preventable harms still continue to pose threat to patients since it was first highlighted in the Institute of Medicines (IOM) report “To Err is human (1999). The year 2000 brought a big storm in the field of patient safety in Healthcare after the publication of IOM’s report “To Err is human” (1999). Its assertion that nearly 100,000 people were harmed each year in United States alone due to several medical errors brought into attention the need of looking at healthcare from different lenses. Since then, several healthcare incidents globally and the shocking performance of the Mid-Staffordshire NHS trust in the UK where 1200 patients nearly died over a decade demanded for developing high reliability healthcare processes. There is great opportunity for healthcare to learn from organisations operating in high risks environment but consistently performing safely and reliably such as airline and nuclear industry (Woods-Hill and Bird, 2019). HRO can be defined as developing resilient and flexible processes and practices in an organization to achieve and sustain highest levels of reliability (Hopkins, 2007).
The design features or guiding principles of the HRO are presented in the table 1.

</tbody>
</table>

Researchers have argued that every organization need to identify and understand the characteristics and behaviours to create conditions to achieve highly reliable performance (Weick and Sutcliffe, 2007; Martin et al., 2015). Table 1 summarises the key characteristics exhibited by HRO and challenges faced by organizations to embed those practices. The next sub-section focuses on literature linked to use of experiential patient feedback from social media for improving quality of care.

**Social Media and Experiential Patient Feedback**

Healthcare previously has been managed by interpersonal communication between the patient and their healthcare providers typically by one to one and face to face arrangements. However, this traditional method of garnering patient feedback are costly to administer and suffer from response bias (Greaves et al., 2012), and it may take few months to get a response to a patient feedback or complaint (Rozenblum et al. 2017). Patient Feedback is one of the core aspects in improving the healthcare service delivery at the hospitals (Rozenblum et al., 2017; Sheard et al., 2017). Feedback through on-line platform including social media and other sources has gained tractions in the last one decade (Adams, 2011; Griffiths and Leaver, 2018). More and more patients have been increasingly active online since 2004, utilising social media platforms and websites to engage and communicate with their healthcare providers (Hamm et al., 2013). Nowadays
patient find it easy to report their healthcare experience using platforms such as blogs, social media, wikis and on health care rating websites (Greaves et al., 2012; Rozenblum et al., 2017). Platforms such as Twitter and Facebook have now become an easy and less expensive source for collecting unsolicited and real-time feedback from patients/ their families, which not possible by the traditional feedback systems (Hawkins et al., 2015).

Access to readily available feedback on micro blogging website such as Twitter or social media platform such as Facebook needs to be carefully interpreted and used beyond its face value (King et al., 2013). The limitations of data generated from Twitter and other online feedback systems can be manifold – validity of story (Lague and Greaves, 2015); not representative of entire population (King et al., 2013); biased opinions, retweets, misrepresentation, confidentiality issues, and limited regulations (King et al., 2013; Rozenblum et al., 2017). Other alternative web platforms such as kiesBeter.nl (Choose Better) in Netherland or NHS choice, and Care Opinion in the UK, provide an online space to patients so that health services can be reviewed (Adams 2011). Such websites provide a platform to patients and family where they share their experience about healthcare professionals, organisation, treatment or service they receive. The growing number of ‘share your experience websites’ for collective benefits provide patients with opportunity to compare the information online and leave feedback at right places. Such information by the online websites are than repackaged for the use of different stakeholders like hospitals (Adams, 2011; Rozenblum et al., 2017; Sheard et al., 2017).

In spite of certain limitations highlighted in the use of online feedback stories, several benefits have been reported by researchers from the use of real-time and unsolicited feedback (Baines et al., 2018). The benefits can be varied from improvement in the service delivery of healthcare provider (Gibbons and Greaves, 2017) to patient taking informed decision about their choices based on the online feedback and provides relevant information about healthcare quality (Greaves et al., 2012). Acknowledging the ambivalence of feedback and integrating it as a part of care will offer useful sensibility for executing feedback schemes in practise and sharing the same can be productive (Ziewitz 2017). Rozenblum et al. (2017) reported that learning from patient experience feedback such as the Care Opinion Website in UK helps in determining the ways in which the organisation can improve patient engagement. This shift from provider focused to patient centric will inculcate continuous improvement in the services thereby enabling them to embed the culture of learning using patient feedback into their organisation (Rozenblum et al. 2017).

The relationship between using data from social media platform to make informed changes in healthcare processes and practices, and its impact on transitioning towards HRO is a research gap that will be addressed in this paper. Authors will analyse the findings from the semi-structured interview, conducted with Care Opinion and the selected English NHS Trust, by using the guiding characteristics of HRO presented in table 1.

Methodology
The exploratory nature of the research questions leads to an adoption of an exploratory case study design (Barratt et al., 2011). The case study was conducted in the Care Opinion and a selected Hospital in the English NHS Trust that can be considered as active user and responder to patient feedback received from CO website. The selected hospital was one among 23 hospitals in England that was deemed as ‘adequate’ by Care Quality Commission (CQC), an organisation responsible for ensuring the quality of healthcare in England by aggregating large number of quantitative measures to identify risks in the quality of care. The case hospital still remains under special measures of
CQC. The ‘special measure’ tag forced the selected hospital to subscribe to CO services to become more patient-centric and be quick in responding to patient feedback, thereby making necessary and safe changes to their practices and processes. In less than three years of their journey with CO subscription, they have made significant changes in the way feedback is managed in the hospital for improvement and learning.

A mixed-method approach to the data collection was adopted for this study. Seven semi-structured interviews with clinical staff were triangulated with crowdsourcing data linked to the hospital and documentary evidence provided by participating hospital. Interviewees included members from all three levels of the hospital such as Patient Safety Director, Consultant, Improvement Specialists, Matron and Nurses. Each interview lasted from thirty minutes to sixty minutes. Authors also conducted interview with two executives of CO including CEO and moderation expert. Both interviews lasted for approximately one hour. The interviews were transcribed and analysed with systematic, iterative coding of verbal data for rich findings (Khan, 2014). The interview data was analysed based on common patterns and insights given by the interviewees. The codes generated were divided into common categories (Miles et al., 2013) linked to outcomes from experiential patient feedback and were mapped against the five characteristics of HRO to have a meaningful analysis and explore relationship between experiential patient feedback and HRO characteristics. Ethical considerations were crucial and were discussed openly with all staff involved prior to the study. The staff was selected based on their willingness to participate in the study. All the data was pseudo anonymised and all the identifiable for the participants are removed and stored as per Data Protection Act 2018.

**Findings**

Care Opinion is an online platform where patients can share their stories and experience which is then prioritised, moderated and packaged back to different stakeholders like patients, healthcare providers and regulators. In the UK, currently 550 organisations use CO out of which 100 have paid subscription. The hospital response rate in Scotland was found to be 96%, for England its 80% and 40-50% for Wales. The selected hospital has taken subscription service for over 18 months, since it came under special CQC measure, and believes it as a great tool to get unsolicited and real-time feedback from patients and their families. CO also combine stories from NHS Choices, another feedback platform used by NHS England to get patient feedback, and pass it to hospitals in a similar fashion.

The CEO of Care Opinion explained the two types of subscription model to receive online feedback – *basic subscription* is free for any hospitals in the UK, but a paid subscription service will give valuable access and advantage to the participant hospital including directly sharing the feedback with right department involved in the posted story. The Associate Chief Nurse (ACN) quoted that the benefit of paid subscription was that feedback reaches to the right level of organisation in real-time. The senior management and clinical team supported the use of CO services by staff members.

The Associate Chief Nurse confirmed that 90% of their feedback is of positive nature and other 10% are mixed. All interviewees concurred that they receive more positive feedback, which is morale booster in a highly pressurised and busy environment. Positive stories get shared via intranet and Twitter, celebrated with everyone and staff gets appreciation and a certificate of recognition. In case of negative stories, they are also looked on immediate basis. An email from central team is sent requesting an urgent response to critical stories from the relevant department which can later be followed if there is a change made. The response is monitored and the staff is reminded that they need to respond in case they forget in their busy schedule. The author of the story is...
informed of any changes made in the system as a result of their feedback.

There was strong opinion in general from all the interviewees that online patients can be more open and honest as they can remain anonymous. Hospital staff believes that online presence changed the perspective and the way they interact and communicate with the patients. The Service Improvement Leader (SIL) in the hospital quoted “happy patient means happy staff” and explained that patient mostly share honest feedback which is very valuable for the team to understand and address the issue. The Deputy Complaint Manager (DCM) of the hospital reported that it is much easier to give online feedback as traditional method of collecting patient feedback can be cumbersome and time taking. More importantly, those feedbacks were dealt centrally first before it can reach right department after significant time delay. After subscription was gained, staffs from relevant department can now respond to their own feedback directly. This is crucial as the feedback comes from the department directly accountable for the issue reported. This further helps in resolving the issue more quickly and efficiently. However, Service Improvement Leader felt that there is a limit to a response which a staff can post online as sometimes the information can be misconceived and there are issues which can be dealt in a better way if done face to face.

The stories posted can be seen by anyone from staff in an email alert but because it is tagged with the relevant department, it becomes their responsibility to respond to it. This is in accordance with ‘accountability’ and ‘empowerment’ theme under ‘deference to expertise’ characteristics of HRO (see table 2). In this way, staff members have engaged more by listening to stories and responding to them to close the loop. Training was provided by the central team and patient experience team to all subscribing members on how to respond to different types of feedback. The central team encourages the staff to respond however do provide support in responding to a negative feedback. The Ward Clerk (WC) suggested they feel good about senior management team promoting individual in each ward to improve quality of care and encourage them to always follow up a negative feedback and close the loop. This also assures that an action is being taken or changes are made to address the patient’s feedback. Discussions revealed that staff can sometimes feel anxious and worried about not only receiving a negative feedback but also responding to it publicly on an open platform. Also Service Improvement Lead is wary about negative feedbacks as some feedbacks can be “really nasty and exaggerated, responding them with a thank you for feedback can sometimes be really difficult especially when they are misrepresented”.

*ACN- Assistant Chief Nurse; DCM – Deputy Complaint Manager; SIL – Service Improvement Lead; MM- Maternity Matron; WC – Ward Clerk; DN- Director of Nursing; HA-Head of Audiology*

There are many examples given by NHS staff about changes made following patient’s feedback, either received through traditional method or CO. The Ward Clerk provided an example where an idea of introducing a colour coded tray came from a nurse in the care ward, after receiving complaints from patients and their families, to provide extra
assistance to older patients that are at the risk of dehydration or malnutrition. Another example of improvement was provided by Deputy Complaint Manager who received complaint from CO about conflicting information given to mothers’ breastfeeding their babies. This was immediately rectified by dedicating a special team and providing extra training to all the staff in that ward. Hospital staff remain optimistic that such changes in hospital not only make them better but also instil confidence amongst patient and their family about the high standard of safety culture in the hospital.

The brokerage firm such as CO has an important role in enhancing patient safety as it allows hospitals to use the patient feedback data for making improvement in the quality of care and thereby exhibiting characteristics of HRO, i.e. engaged leadership, enhanced safety culture, effective communication, teamwork, empowerment, accountability, effective reporting and feedback, and robust process improvement (see table 2). From the interviews, it is understood that patient experience has drawn a great deal of importance in terms of improving the healthcare service delivery. The patient stories are being heard and is considered to be important for the hospitals in their journey to embed the culture of learning with strong patient safety culture thereby exhibiting characteristics of HRO. The case analysis facilitated in identifying examples and methods on how selected case hospital used patient feedback for making informed changes at all levels in order to aspire to operate as error-free highly reliable healthcare organization. The process of implementing a change in the organization is undoubtedly a difficult task to perform but by utilizing this case study a direction for improvement in the quality of care can be obtained.

**Discussion and conclusion**

Literature highlighted an increasing organisation awareness in the importance of listening to stories of patient experience posted on different online platforms (Ziewitz, 2017; Sheard et al., 2017; Franceet al., 2011; Frank, 2013). The results from the findings are similar and suggests that patient feedback holds immense value for NHS in their improvement journey. The spread of new technologies is ever growing and in this era of digitalisation, there is a dramatic increase in patients using online and social media platforms to share their experience. Findings are in line with the literature - stories are more visible online and hospital staff engagement with public has improved as a result of such visibility (Hamm et al., 2013; Rozenblum et al., 2017; Griffiths and Leaver, 2018). Nonetheless, there was element of anxiety and discomfort among staff members initially when dealing with negative feedback as it brings them or their ward into centre of attraction and discussion. Similar to literature findings, the CO staff also expressed their concern about confidentiality issues and misrepresentation, even after high quality moderation process, that may cause discomfort at patient or hospital end (Lagu and Greaves, 2015; King et al., 2013).

The CO platform provides an opportunity for patient and family to share “truth based personal experiences” Borkman (1976), and majority of the interviewees conceded this statement by stating online patients can be more open and honest about their experience and interactions with providers as they can remain anonymous. Interviewees from both CO and NHS also concur with findings reported by Greaves et al. (2012), that online feedback is easy and less time consuming for patient’s than traditional methods. It also ensures quick and timely response without the requirement to fill length forms. Similar findings were reported in literature (Rozenblum et al., 2017; Hawkins et al., 2015)-approaching hospitals directly may involve filling up lengthy forms and giving out

---

8
Does increased number of subscription and listening to CO stories leads to exhibiting HRO characteristics? The selected case hospital from England demonstrated significant improvement in their care process and practices by proactively listening and responding to patient feedback posted on the CO website. Majority of the staff in the selected hospitals are active on Twitter. As a result, Twitter is used as a real-time communication mechanism for sharing any learning from improvements or mistakes (i.e. exhibiting ‘sensitivity to operations’ and ‘preoccupation with failure’ characteristics) and recognising an individual or team for enhancing safety culture and conducting improvement, aligning with findings from Adam (2011) and Rozenblum et al (2017). The subscription services also brought structural changes in the way feedback was managed – moving the control from the central team to local ward and employees who are now accountable for responding to feedback and take actions for improvement. This is aligned with ‘deference to expertise’ and ‘sensitivity to operations’ characteristics of HRO (Chassin and Loeb, 2013; Hopkins, 2007).

There were few feedbacks that cut across organisational boundaries and required systems thinking approach to problem solving. This was achieved by active coordination and teamwork between different wards managers and clinical staff to implement improvement actions and close the loop (Martin et al., 2015; Sheard et al., 2017). This is a good example where ‘reluctance to simplify’ and ‘commitment to resilience’ characteristics were met. Adams (2011) questioned the transparency and reflexivity of online feedback, and our study identified that staff were concerned about patient’s sometimes exaggerating their issues online and warning other users to avoid consuming such service. However, these feedbacks are based on individual perception and their encounter which may not be representative of the services offered by the ward or hospital. In spite of the anxiety and discomfort, interviewees revealed that patient’s stories help them to identify common themes and patterns and improvements made from listening to feedbacks are on rise recently. It also prompts for cross-functional team work for problem solving and reflection. Thus, exhibiting such practice and behaviour helps staff members to embrace HRO characteristics of ‘reluctance to simplify’, ‘sensitivity to operations’ and ‘commitment to resilience’.

The ability to use patient and family members’ perspective can be a useful tool for both patients and health care workers (Greaves, 2012). It has been demonstrated from this case study that if experiential patient feedback data is implemented in practice and treated as an integral part of care, then patient-centered changes can be implemented across the organization which can lead to high quality of care provision and less errors. The subject of patient safety is of vital importance as is HRO and healthcare processes/organisations. This study has taken an organisational perspective to close the gap in knowledge concerning the design of relevant and reliable models of care.

Time and resource constraints led to reliance on a single case study to conduct the research project. Focusing on a single case study has obvious limitations. However, the data collected via interviews with the key participants from different hierarchical levels from two organisations helped to achieve the aim of the study. This case study can be considered as a pilot study. There is a scope in future where data from multiple hospital can be compared and contrasted to conduct in depth analysis in order to evaluate the impact of patient’s feedback on overall improvement of service delivery. A large sample size will provide more reliable data for analysis. Further research can focus on understanding the level of engagement of different healthcare departments in rolling out the patient feedback for organizational learning. This study includes the staff’s viewpoint...
on patient’s story, further research can also be carried out by involving patients and relatives who are actual authors of the feedbacks to understand how they are impacted as a result of feedbacks they share.

Improving productivity of hospital operating rooms (ORs): the case of a public hospital

Gad Vitner (gadiv@ruppin.ac.il)
Ruppin Academic Center

Abstract
The purpose of this study is to develop an improved scheduling methodology to increase productivity by reducing idle time and overtime. At present, the hospital utilizes the methodology of allocating fixed blocks of ORs for a given clinical department on a yearly plan based on surgery types forecasting. The recommended approach (Modified blocks) allocates just a given percentage of ORs time (e.g. 75%) as fixed blocks and the remaining hours are flexible allocated. The improved scheduling model used 80% of the capacity. It resulted with an improvement of 87% in regards to overtime and with no idle time.

Keywords: Operating room, Productivity, Public hospital

Introduction
Operating rooms (ORs) are resource intensive and costly hospital units. Since ORs are the hospital's largest cost and revenue center, maximizing its productivity is essential to maintaining an economical viable institution (Guanlian, et al., 2018). Increased healthcare costs are pushing hospitals to reduce costs and increase the quality of care. Operating rooms are the most important source of income and expense for hospitals. Therefore, the hospital management focuses on the effectiveness of schedules and plans (Gur and Eren, 2018). Managing the operating theatre, however, is hard due to the conflicting priorities and the preferences of its stakeholders, but also due to the scarcity of costly resources. Moreover, health managers have to anticipate the increasing demand for surgical services caused by the aging population. These factors clearly stress the need for efficiency and necessitate the development of adequate planning and scheduling procedures (Cardoen et al., 2016). Numerous factors constrain OR productivity including, infrastructure, human resource management issues, scheduling variation, process flow, technology issues and information management limitations. One common methodology of ORs capacity allocation is booking block of days/hours to a given clinical department in the hospital. This booking procedure frequently results in idle time or overtime, thus increasing costs and patients waiting time. Other problematic issues are the variability of operating hours (even for the same type of surgery) and the set up periods needed between two operating procedures (Gauthier and Legrain, 2016). Many hospitals allocate blocks of OR time to individual or groups of surgeons as guaranteed allocation, who book surgeries one at a time in their blocks. The booking procedure frequently results in
unused time between surgeries (Li et al., 2016). Realizing that this presents an opportunity to improve OR utilization, hospitals manually reschedule surgery start times one or two days before each day of surgical operations. A rescheduling problem was developed as a variant of the bin-packing problem with interrelated items, which are the surgeries performed by the same surgeon. A lower bound (LB) construction algorithm was developed and proved that the LB is at least (2/3) of the optimal staffing cost. (Li et al., 2016), implemented a discrete-event simulation model to understand how changes to the Master Surgery Scheduling (MSS) would affect bed occupancy, thereby providing business intelligence for short- and long-term hospital planning. A decision tool was subsequently developed for hospital managers to test different scenarios. Simulation results showed that significant bed occupancy levelling could be achieved through small and practicable changes to the MSS. Optimisation routines conducted using the simulation model then gave additional insights into how the schedule should be revamped for the long term.

In the literature, there is unanimous consensus that OR performance depends strongly on how surgical activities are scheduled (Litvak and Long, 2000), There is also consensus that the scheduling process comprises three sequential stages (Beliën and Demeulemeester, 2007). (i) case-mix planning, (ii) master surgical scheduling (MSS) and (iii) patient selection and sequencing. The aim of the first stage is to establish the total amount of OR time to be assigned to each surgical specialty, usually on a yearly basis. The second stage involves determining the specialty (or specialties) to assign to each OR for each day of the planning horizon (e.g. two weeks or one month) and, sometimes, the number and types of surgery to be performed each day. Finally, the third stage involves selecting and sequencing patients to undergo surgery in the coming week. The study suggests that creating an effective operating room scheduler requires clustering patients in homogeneous surgery groups and developing a flexible tool that allows: scheduling surgery groups instead of actual patients, easily adding/removing constraints, changing the objective function(s) and adjusting the planning horizon (Yip, et al., 2018).

Visintin et al., (2017) and Samudra et al., (2017) found that it is important to model non-elective arrivals and to include elective rescheduling decisions made on surgery day itself. Rescheduling ensures that OR related performance measures, such as overtime, will only loosely depend on the chosen patient scheduling method. They also found that capacity considerations should guide actions performed before the surgery day such as patient scheduling and patient re-planning. The common practice in hospitals is to use mean arrival and processing times for OR planning. However, in a highly stochastic health care system, it is necessary to account for variations in patient arrivals and processing times. Gunna et al., (2017) deal with the dynamics in processing times and patient arrivals. They propose an optimization model for OR block scheduling by using the portfolio selection (PS) technique to maximize patient flow and benefit.

Vali-Siar et al., (2018) investigated a multi-period and multi-resource operating room integrated planning and scheduling problem under uncertainty. To this end, a mixed integer linear programming model has been developed for minimizing the tardiness in surgeries, overtime and idle time. Constraints related to human resources, equipment, as well as beds in pre-operative holding unit, recovery unit, ward and intensive care unit are taken into consideration.

Al-Refaie et al., (2018), propose optimization models for multiple-period scheduling of patients in ORs as well as for sequencing of patients in the operating theatre. The first model considers scheduling at a minimal total cost, comprising
hospitalization, under-time, overtime, and cancelation costs. The second model involves patient sequencing in the operating theatre at a minimal total overtime cost. The research results are expected to improve patient satisfaction and resource efficiency as well as reduce hospital expenses by minimizing overtime, under-time, hospitalization costs, and cancelation costs. Emergencies occur frequently in hospitals, and the number of lives saved should be maximized. Because emergency patients disrupt established schedules of hospital operating room, proactive techniques should be employed to save as many lives as possible. Al-Refaie et al., (2018) developed three optimization models for optimizing OR scheduling during unexpected events and accommodating emergency patient surgeries in the established schedule. Molina-Pariente et al., (2018) address a stochastic operating room scheduling problem which consists of assigning an intervention date and operating room to surgeries on the waiting list, minimizing the under- and overtime costs of the operating rooms, and the cost of exceeding the capacity constraints of the system. Uncertainties in surgeries duration, in the arrivals of emergency surgeries and in surgeons’ capacity are considered. The study proposes a Monte Carlo optimization method based on the sample average approximation method, which combines an iterative greedy local search method and Monte Carlo simulation.

Block scheduling is a combination of surgery types that can be performed in the same operating room on the same day of the planning horizon. Benchof, et al., (2017), report on the development and implementation of an integer programming model to generate a near-optimal block schedule. The approach differs from many in the literature because it considers both direct nursing costs and patient-related costs, and can accommodate a variety of practical constraints. Three major benefits of the schedule are that it: (1) satisfies almost all of the monthly block requirements in only four weeks, thereby releasing capacity to reduce the surgical backlog; (2) eliminates days with excess admissions, which would have required additional nursing staff; and (3) reduces the number of surgeries cancelled due to an insufficient number of available beds.

The allocation of surgeries to ORs is a challenging combinatorial optimization problem. There is also significant uncertainty in the duration of surgical procedures, which further complicates assignment decisions. Denton et al., (2010) presented stochastic optimization models for the assignment of surgeries to ORs on a given day of surgery. The objective includes a fixed cost of opening ORs and a variable cost of overtime relative to a fixed length-of-day.

Yahia et al., (2016) generated an optimal case-mix plan of surgery patients with uncertain surgery operations, which includes uncertainty in surgery durations, length of stay, surgery demand and the availability of nurses. In order to obtain an optimal case-mix plan, a stochastic optimization model was proposed and the sample average approximation method is applied. The model is used to determine the number of surgery cases to be weekly served the amount of operating rooms' time dedicated to each specialty and the number of ward beds dedicated to each specialty. The optimal case-mix selection criterion is based upon a weighted score taking into account both the waiting list and the historical demand of each patient category. The score aims to maximizing the service level of the operating rooms by increasing the total number of surgery cases that could be served. The results show that the stochastic model solution outperforms the expected value problem solution.

In general, multiple surgeries are carried out in the same OR every day. Each surgery may have a random duration, which results in room idle time and patient waiting time. One of the major factors affecting the idle and waiting times is the
schedule of surgeries in the OR. To better sequence multiple surgeries to reduce idle and waiting time, an effective performance evaluation method is needed. Zeng, et al., (2018) introduced an analytical model to evaluate the performance of OR schedules. First, closed formulas to evaluate the case of two surgeries are developed and used as a building block in subsequent studies. Then, an iteration procedure is presented by aggregating every two surgeries into one using the two surgeries formula, and continuing to approach the next one, until all surgeries are aggregated into one. Using such a model, the expected idle time and waiting time for a given surgery schedule can be calculated quickly and accurately.

Methodology

The public hospital

The medical centre under study serves a population of about one million children, adults and elderly people. It manages 800 beds in various clinical departments and 21 operating rooms. In 2017, there were 160,000 visits to the emergency room, 21,000 surgeries were conducted, 64,000 were hospitalized and delivered 9,000 new borns. The medical centre is approved to the JCI (Joint Commission International) standard.

The operating rooms division

The division performs three types of surgeries: Emergency/unplanned surgeries, elective/planned surgeries and ambulatory surgeries where the patient is discharged when the procedure is completed. The ORs operate as follows: elective and ambulatory procedures are performed five days weekly during the first shift between 07:00-15:00. Other procedures are conducted upon demand during the second (15:00-23:00) and the third (23:00-07:00) shifts. Figure 1 illustrates the 2017 operations distribution per department.

![2017 ops. distribution per dept.](image)

A Pareto analysis reviles that general/vascular/orthopaedic/gynaecology/paediatric surgeries are about 70% of all the operations performed. General surgeries department
is the most users of the ORs with 16% of the operations. Table 1 presents the weekly allocation of ORs per department.

It should be noticed that room number 8 is available during the week for emergency/unplanned operations. Figure 2 illustrates the weekly hourly plan.
Weekly allocation of ORs is conducted on a yearly basis according to past demand and future forecast. The Block Scheduling Strategy is used. The allocation algorithm is based on a weighted average index contains a set of parameters for each department. Figure 3 presents the set of parameters and the related weight.

This methodology of fixed allocation per department creates two problematic issues: a. demand for over time for some departments and b. low efficiency/idle times for other departments. Figures 4, 5 present actual versus planning hours for general surgery and neurosurgery departments accordingly.

![ORs capacity allocation](image)

**Figure 3 – Allocation parameters weights**

![General Surgery (actual vs. planning)](image)

**Figure 4 – General surgery actual vs. planning hours**
Observing the above figures demonstrate the problematic issues where regarding general surgery the allocation method creates over time while for the neurosurgery it creates idle time.

The improved scheduling methodology
There are three common strategies to schedule ORs in hospitals: a. Open scheduling- allocate the first available room; b. Block scheduling- allocate fixed blocks for a given department and c. Modified block strategy- Integration of strategies a and b. Allocation is conducted in two steps. 1. Decide upon a fixed percentage for the block scheduling and 2. Using the open scheduling strategy for the remaining ORs hours (Fei et al., 2010). Figure 6 presents simulation results for the best percentage in regards to over time to be 80%.

The improved methodology is conducted in two steps: 1. each department gets 80% of the present weekly plan and is responsible to define the sequence of surgeries in its assigned ORs. The Longest Process Time (LPT) heuristics was used and 2. An independent person will get seven days in advance the rest of needed ORs of all the departments and will perform allocation to minimize over time. In order to optimize
these 20% of ORs hours, the Mixed Integer Nonlinear Programming (MINLP) was used to minimize the number of overtime hours (Zhaoxia and Xueping, 2014).

The recommended Modified Block Strategy was tested and showed an improvement of 87% in regarding overtime with no idle time.

Summary and Conclusions

In many post-industrial societies, health care industry is one of the largest industries in the service sector. Health care expenditures have been increasing rapidly for the last few decades, and will reach 19.5% of the US GDP by 2019. ORs are usually the most critical resources in hospitals. In some hospitals, more than 40% of the total revenue comes from ORs, and the ORs consist of a large proportion of the total expenses. Research indicates that in some situations, the ORs have not reached the target utilization, and a better surgery-to-OR scheduling strategy is needed to improve the utilization level and thus achieve cost savings.

As mentioned above, ORs are resource intensive and costly hospital units. Since ORs are the hospital's largest cost and revenue centre, maximizing its productivity is essential to maintaining an economical viable institution.

The medical centre under study serves a population of about one million children, adults and elderly people. It manages 800 beds in various clinical departments and 21 operating rooms. In 2017, there were 160,000 visits to the emergency room, 21,000 surgeries were conducted, 64,000 were hospitalized and delivered 9,000 new-borns. The medical centre is approved to the JCI (Joint Commission International) standard.

Weekly allocation of ORs is conducted on a yearly basis according to past demand and future forecast. The Block Scheduling Strategy is used. This methodology of fixed allocation per department creates two problematic issues: a. demand for over time for some departments and b. low efficiency/idle times for other departments.

An improved scheduling methodology was developed based on the Modified block strategy. The improved methodology is conducted in two steps: 1. each department gets 80% of the present weekly plan and is responsible to define the sequence of surgeries in its assigned ORs. The Longest Process Time (LPT) heuristics was used and 2. An independent person will get seven days in advance the rest of needed ORs of all the departments and will perform allocation to minimize over time. In order to optimize these 20% of ORs hours, the Mixed Integer Nonlinear Programming (MINLP) was used to minimize the number of overtime hours. The recommended Modified Block Strategy was tested and showed an improvement of 87% in regarding overtime with no idle time.

Abstract

2017-2018 was the worst US flu season since the 2009 H1N1 pandemic. However, the mortality rate of hospitalization cases in 2017-2018 was almost doubled than what it was during the pandemic. A hospital case is used to illustrate unexpected strong relationships and outcomes of how the disruption in the IV-bags supply chain during hurricane Maria in Puerto Rico, 2017 may have affected the number of deaths in 2017-2018 U.S. flu season. This event showed how the American healthcare system may have significant high public health risk caused by supply chain disruption, especially due to the location of pharmaceutical plants.

Keywords: Hurricane Maria, Flu season, Risk Management, Supply Chain

Introduction

In September 20, 2017, Puerto Rico was slammed by a category four storm with violent winds and screeching rains that terrified the island population for 72 hours and was later known as Hurricane Maria. It caused $90 billion in damage and a reported death toll of 2,975. It was about 11 months until power was finally fully reestablished in the island. Transportation of people and goods that has always been a challenge in Puerto Rico, became almost impossible after Hurricane Maria. To the point that, a year later Maria’s landfall, when asked where more recovery resources should be put on, 93 percent of Puerto Ricans point to the island’s crumbled roads and busted highways, outranking other major priorities, such as the repair of damaged houses, hospitals, the power grids, and the fact the island had to permanently close 283 public schools. “We got more craters here than the moon” (Hernandez, 2018; Kaiser Family Foundation, 2018; CENTROPR, 2018).

Despite all the island precarious infrastructure, it has a long-lasting relationship with American health care companies. U.S. relies on Puerto Rico for many key medical products. Almost 10% of pharmaceutical expenditures by Americans are for products manufactured in Puerto Rico; with many important drug categories including oncology drugs, HIV drugs, and blood fraction products. Puerto Rico produces more pharmaceutical products for the U.S. ($40 billion) than any part of the world (Dooren, 2017). The next largest producer is Ireland, from where it imports nearly $20 billion. Puerto Rico also produces more pharmaceuticals than any American state (by dollar value). The next largest producers are Indiana and California, but Puerto Rico produces more pharmaceuticals than both of these states combined (Dooren, 2017).
One of these critical pharmaceutical products that is mainly just produced in Puerto Rico is a bag containing a saline solution in a diluent form (0.9% sodium carbonate) used to deliver a variety of parenteral medications called IV bag. This a critical medication for any patient under hospitalization. The United States gets almost the totality of its saline supply from just three companies: Baxter International, B. Braun Medical, and ICU Medical. One of these companies, Baxter, located in Puerto Rico, supplies almost 50% of all US Hospitals (Mazer-Amirshahi & Fox, 2018). The inventory level for the IV bags has been a constant challenge since 2013 for healthcare providers. The shortage of saline solutions has worsened, and its supply chain has not been fully recovered when a severe rupture in saline manufacturers supply chains occurred after Hurricane Maria (E. Fox, 2018; Loftus, 2017). The saline components delivered through the IV-Bags are basic drug required by virtually all hospitalized patients, either as a component of a medication infusion or as hydration, resuscitation, or irrigation fluid (Azghandi et al., 2018; Mazer-Amirshahi & Fox, 2018). The lack of an IV bag presents risks to the patient’s health as a result of no-treatment, undertreatment and possible medication errors due to attempts to replace missing drugs (WHO, 2016), which can eventually impact in the increase of death rates.

The U.S. Center for Disease Control and Prevention (CDC) estimates that the 2017-2018 was one of the worse flu seasons in the American history. The number of cases of people who got sick was the highest (48.8 million) since the 2009 H1N1 pandemic (60 million). Even though official reports by the CDC do not consider anything related to the shortage of IV bags as possible causes for a particularly deadly flu season, it was not rare to witness media outlets featuring that possibility during the peak of the problem. "If we can't support patients coming in emergency rooms who have the flu, more people are going to die," predicts Deborah Pasko, director of medication safety and quality at the American Society of Health System Pharmacists, a professional group. "I see it as a crisis." (Johnson 2018). Different supply chain problems were also exposed. “Most IV saline bags used in U.S. hospitals are made in Puerto Rico. Hurricane Maria has shown how troubling it can be to rely on one producer” (Wendelbo and Blackburn, 2018).

Considering the relevance and complexity of supply chain management in the pharmaceutical industry and the possibility that the lack of IV bags may have contributed to the deaths from influenza in the severe 2017-2018 flu season in the United States, we pose the following research question: How the disruption in the IV-bags supply chain during hurricane Maria in Puerto Rico, 2017, affected the number of deaths caused by the 2017/2018 flu season in the U.S.? Historical data on influenza deaths in recent decades, news, government agency documents, and other documents are considered in our analysis. We also used a large not-for-profit hospital in the Midwest to illustrate the relationship between the shortage of IV bags and deaths from influenza related illness.

**Literature Review**

Pharmaceutical supply is composed of four main levels: chemical plants, pharmaceutical plants, distribution affiliates, and healthcare facilities (Burns, 2002; E. R. Fox et al., 2009). Pharmaceutical shortage can be addressed through varying strategies introduced in each of these levels. Drug shortages in any the four pharmaceutical supply chain levels affected directly patients causing significant safety concerns (Saedi, Kundakcioglu, & Henry, 2016). They result in inconvenience and/or profit losses and pose a health risk to patients due to inadequate, interrupted, or lack of treatment (WHO, 2016).
In general, the research of pharmaceutical supply chains has been approached from managerial analysis or quantitative modeling (Azghandi et al., 2018; Saedi et al., 2016). Managerial approaches include vendor managed inventory (VMI), outsourcing, supply chain integration, and risk management in pharmaceutical supply chains (Saedi et al., 2016). Studies on disruption mitigation in pharmaceutical supply chain management are related in the scope of the types of disruptions, mathematical modeling supply chain and response strategies has been conducted for other industries (Azghandi et al., 2018).

There are many different approaches for mitigation of disruption risks that have been examined. Common tactics for alleviating the effects of disruptions are financial mitigation, operation mitigation, and operational contingencies (Brian Tomlin, 2006). Mitigation tactics are those in which the firm takes an action in advance of a disruption and correspondingly incurs the cost of the action regardless of a disruption’s occurrence. Operational tactics, such as inventory management, multiple sourcing, and flexibility in production are also studied in the literature of supply chain disruptions.

There have been many works regarding supply chain risks in general, and disruption uncertainty in particular. Researchers from the supply chain rupture area demonstrate that an optimal strategy to implement when dealing with a rupture varies based on the characteristics of the interruption (Chopra, Reinhardt, & Mohan, 2007). Tomlin (2006) suggests inventory strategies, dual sourcing, and acceptance to deal with disruptions, and demonstrates that the optimal strategy changes as the disruptions become longer or more frequent. Chapman et al. (2002) discuss supply chain vulnerabilities by enumerating sources of disruptions and analyzing the impacts of each. Mitroff and Alpasan (2014) provide strategic tools to help identify stress causes and their impact on a firm’s preparedness towards disruptive events. Kleindorfer and Saad (2005) chart a conceptual framework that trades off risk mitigating investments potential losses caused by supply disruption. Ritchie and Brindley (2007) also build an empirical framework that addresses the question of choosing a set of suppliers that minimizes loss caused by deviation, disruption, and disaster risks. Atan et al. (2016) present hybrid strategies to deal with supply uncertainty or demand uncertainty in multi-segment supply chains. They consider the interruptions that occur at a specific location and demonstrate that an optimal policy to deal with an interruption in supply uncertainty is not the same as the optimal policy to deal with an interruption in demand uncertainty.

Puerto Rico and the Life Science Industry

Puerto Rico, officially the Commonwealth of Puerto Rico, is an island territory of the United States, located in the northeast Caribbean Sea (Rodríguez-Díaz, 2018). Puerto Rico’s pharmaceutical and medical device manufacturing industries are integral to the Island’s economy. In 2016, approximately 30% of Puerto Rico’s GDP was composed of pharmaceuticals and medical devices manufactured on the Island and these products were two of Puerto Rico’s largest exports (Dooren, 2017). Medical product manufacturing help support a highly skilled workforce in Puerto Rico. Residents employed in the drug and medical device industries collectively earn approximately $800 millions in wages in one year and this industry employs about 90,000 people, which represents about 30% of all manufacturing employees in Puerto Rico (Dooren, 2017). An important fact to consider and understand the even greater importance of this industry to Puerto Rico economy is to look at Puerto Rico’s wealth. Puerto Ricans, despite being considered American Citizens, make way less money than their counter parties in the US mainland—Puerto Rico household annual income (20,078) is 65% lower than the US median household income ($57,617) (DATAUSA, 2019). A combination of more affordable labor, still keeping the production as being “made in
America”, plus an attractive tax incentive package (Reeves, 2017) may have contributed to make Puerto Rico one of the top destinations for Pharmaceuticals and Medical Devices manufacturing companies.

There are more than 1,000 individual drug products that are registered to be manufactured in Puerto Rico; of which several hundred are considered by the Food and Drugs Administration department (FDA) to be medically important (Dooren, 2017). Puerto Rico manufactures 30 drug products and approximately ten biological devices that are of critical importance. For these, Puerto Rico is a primary for all of them and the sole manufacturing site for at least 14 of them. These drugs do not have clear therapeutic alternatives (Dooren, 2017). The FDA acknowledges the risks related to that and FDA Drug Shortage Teams are carefully monitoring all 40 of these products.

There are more than 80 pharmaceutical and medical facilities owned by companies like Amgen Inc. AMGN, Baxter International Inc., Mylan NV, Johnson & Johnson Inc., Medtronic, and Abbott Laboratories residing on the island (Meagher, 2017). Puerto Rico is home to top multinational pharmaceutical companies operating in more than one site on the island. According the Government of Puerto Rico (2017), two dozen different kinds pharmaceutical products are manufactured in Puerto Rico: antihypertensive drugs, tranquilizers, laxatives, anti-diabetic drugs, vasodilators, antibiotics and contraceptives, among many others. Additionally, 12 of the top 20 pharmaceutical companies have presence on the island (See Figure 1).

**Figure 1** – Map of Puerto Rico’s pharmaceutical manufacturing facilities

**Hurricane Maria’s Effect on IV bag shortages**

Hurricane Maria made landfall in Puerto Rico on September 20, 2017, as a Category 4 hurricane, with sustained wind speeds just below 155 mph, gusts of 175-195 mph, and rainfall of up to 38 inches in some areas (NHC, 2017). Drug shortages and medical device shortfalls abounded as pharmaceutical companies scrambled to find enough diesel to run their factories, deal with power outages, locate and ensure their employees’ safety, and figure out how to transport people to work on obstructed roads (Weber, 2018). While the island lived its worst blackout in history that contributed to loss of
many lives due to power outage in hospitals all over the island, hospitals in the US started to feel those consequences in a different kind of outage.

The devastation caused by the hurricane Maria in Puerto Rico amplified the IV bag shortage in the U.S. hospitals. In particular, sodium chloride 0.9% injection bags, which are ubiquitous in medical facilities and hospitals (Azghandi et al., 2018). Most drug shortages occur with older, generic, injectable medications that are produced by typically three supplier (Mazer-Amirshahi & Fox, 2018). As mentioned before, the U.S. gets its saline from just three companies: Baxter International, B. Braun Medical, and ICU Medical, and about 50% of this supply come from Baxter, which manufacturing sites are located in Puerto Rico. In the past, some shortages were caused by a quality or production problem at the manufacturing facility (E. R. Fox et al., 2009; Mazer-Amirshahi & Fox, 2018). Also, when one supplier experiences a shortage, other suppliers often do not have sufficient manufacturing capacity to make up the difference.

Drug manufacturers are not required to have redundancy in their facilities or even a business contingency plan in case of a disaster, no matter how essential or lifesaving the medication they are producing (Mazer-Amirshahi & Fox, 2018).

After Baxter’s Puerto Rico manufacturing plant was hit by Hurricane Maria, the shortage of small-volume saline bags became more intensive and critical. Baxter had no redundancy in manufacturing capacity for saline bags. The other two IV bags suppliers have not been able to increase their production enough to make up for the shortage either. Saline produced by B. Braun was already in short supply before the hurricane, as the company worked to correct manufacturing-quality problems. The IV bag shortage had begun in 2014, affecting large- as well as small-volume products (Mazer-Amirshahi & Fox, 2018). Large-volume saline products (>500 ml) are typically used as maintenance or resuscitation fluids or for irrigation. Though some shortages of large volume saline solutions are attributable to problems at manufacturing facilities, increased demand for intravenous fluids due to a severe influenza season has also contributed to the current short supply (Mazer-Amirshahi & Fox, 2018).

Unavailable medicines broadly affect the treatment and prevention of diseases. Saline shortages can affect patient care in various ways (Mazer-Amirshahi & Fox, 2018). Medication errors and adverse drug events can result when medications that are typically administered as short infusions are given by intravenous push or when providers choose less familiar but more readily available products as substitutes. Increased ad hoc compounding of drugs may result in dilution errors or microbial contamination, and eventually contribute to increase in death rates.

**Background of influenza in the U.S.: 2017-18 influenza season**

According the Centers for Disease Control and Prevention (CDC), the United States 2017–18 influenza season was a high severity season with high levels of outpatient clinic, and emergency department visits influenza-like illnesses (ILI), high influenza-related hospitalization rates, and high and geographically widespread influenza activity for an extended period (Garten et al., 2018). ILI activity during the 2017-2018 season began to increase in November, reaching a period of high activity during January and February nationwide and remaining high until the end of March. ILI reached a peak of 7.5% weekly outpatient consultations to health service providers participating in the U.S, which was the highest percentage since the 2009 H1N1 flu pandemic (7.7%). Outpatient Influenza-like Illness Surveillance Network (ILINet) was equal to or greater than the national reference level of 2.2% for 19 consecutive weeks (weeks 47-13) during the 2017-18 season.
CDC reports its data in four levels to understand the seriousness of a flu season: number of people who got sick, number of people who seek a health care provider, number of people who were hospitalized, and number of deaths for influenza related illness. CDC believes that the high number of influenza cases in the 2017-2018 was due to a particular strong virus. That theory is reinforced by the fact that a large number of people who got sick (48.8 M) where then hospitalized (959,000), which represented about two percent of all sick cases. The strength of that virus is particular impressive when compared to the pandemic numbers, when 0.45 percent of the people who got sick (60.8 M) had to be hospitalized (274,304). Moreover, another number becomes even more impressive. During the 2009 H1N1 pandemic, 4.5% (12,469) of all people who were hospitalized due to influenza related illness (274,304), died. During the 2017-2018 flu season, this number jumped dramatically, increasing 82% from 4.5% to 8.3% of deaths (10,300) of people who were hospitalized (79,400). When just the number of deaths is compared among the two seasons, the 2017-2018 had almost 700% more deaths in absolute numbers than the 2009 H1N1 pandemic. The number of working adults (18-64 years) who died for influenza related illness was also higher in the 2017-2018 season than it was in the 2009 pandemic. For that reason, the 2017-2018 may be considered the worst flu season in the U.S. history. (Table 1)

As illustrated on Table 1, this paper argues that the 2017-2018 flu season can be considered the worst flu season in the US history. That is also based in the death rate. According to Sundar et al (2011), a death rate due to influenza related illness should range from 1.5% to 6% of the hospitalizations, as illustrated on Figure 2. However, the death rate for all age ranges hospitalized during due to ILI in the 2017-2018 flu season was higher than that, at an 8.3% average. A rate 82 percent higher than the worst record season (2009 pandemic). When compared to the number of sick people, this number is alarming. During the 2009 pandemic, 0.02% of the population who got sick, died from ILI. On the other hand, during the 2017-2018 flu season, this rate was 0.16%, an increase of almost 700%.

**Figure 2.** An illustration of the methodology used to extrapolate death from reported laboratory-confirmed, based on 2009 pandemic  
Source: Sundar et al (2011)
It is well known that children and the elderly are usually the most susceptible to suffer from the flu. However, if we considered the number of working adults (18-64 years) who died for influenza related illness during the 2017-2018 season, that was also higher than those who lost their lives during the 2009 pandemic, we may find another hidden cost of the flu season: the lost income of these working adults during their possible lifetime. To calculate what that could be, we used the US life expectancy in 2017 (80.1 years of age), the average American individual income ($57,652), and the distribution of age range in current US population (US CENSUS, 2018). Considering these data, ignoring other related tangible and intangible costs, those working adults whose lives were lost due to the flu season in 2017-2018, cost the American society, at least $24.2 billion (Table 2)

</table>

There is not much that can be done to treat the flu, and that once the patient is hospitalized, the most important part of his or her treatment involves to keep them hydrated (Ellis, n.d.). Thus, it is possible to see a possible correlation between the problem with the IV-bags supply due to the closure of manufacturing plants during Hurricane Irma in Puerto Rico and the increase of death rates of hospitalized patients to ILI. To test that hypothesis, we performed a case analysis.

Hospital Case Analysis

To illustrate a possible relationship between IV bag shortage and influenza deaths, we used the case of one of the largest US hospitals, located in the Midwest. Among the pharmaceutical supply chain levels, the hospital (healthcare facility) is most affected by shortages because it is in direct contact with patients. We took data from a not-for-profit academic medical hospital for our analysis. The hospital established in 1883, is one of the oldest and most distinguished pediatric hospitals in the United States. It is home to the country’s busiest pediatric emergency department, performs the second largest number of surgical procedures at a children’s hospital in the nation and offer comprehensive clinical services, from treatments for rare and complex conditions to well-child care.

Data analysis and treatment used 262 weeks as a research sample, from week 40 in 2009 to week 8 in 2018. We used multiple regression as a statistical technique to evaluate the association coefficient between the independent variables on the dependent variable, in other words, the degree of alteration of the dependent variable as a response.
to the independent variables (Hair et al., 2009). Therefore, this technique enables an analysis to be made of what contribution each independent variable to the influenza deaths (see Table 3). We considered that there was no variation in vaccination coverage and because that it was used in our model.

The descriptive analysis of data gives the means, standard deviation and minimum and maximum. The existence of standard deviation and a high dispersion of the minimum and maximum values are important because they show the variability of the variables when using regression model. In our model, the variables prove to have a normal distribution. We analyzed the correlation between the research variables using the significant test at the 0.05 level. Hospitalization and IV bag shortage are variables that are positively correlated with influenza deaths, while week indicates a negative and statistically significant correlation. The fact that there is no correlation between the variables is evidence of the absence of a dimensional relationship, in other words, when a variable is interlinked with another. The discovery of these correlations is relevant evidence for the regression analysis. Analysis were then carried out using the multiple regression technique, which shows the causal relationship between variables.

The regression test is shown in the Table 4, the results indicate that there was positive relation between the number of deaths and the IV bag shortages.

**Discussion**

Hurricane Maria have heavily compromised pharmaceutical manufacturing in Puerto Rico and sit the U.S. healthcare system on the brink of a significant public health crisis (Mazer-Amirshahi & Fox, 2018). Saline solutions are used in every healthcare setting that administers intravenous medications in the United States. Larger institutions use hundreds of these bags per day. Hospitals and other healthcare settings have reported critically low on product and unclear as to when their supplies will be replenished, and
the storm exacerbated the situation. Baxter’s central manufacturing plants for its IV-bags had its capabilities going down due to hurricane damage, the saline bags — already limited after an issue with quality at a B. Braun factory and a record flu season — were in even shorter supply (Weber, 2018). Hospitals and medical establishments across the country dealt with what they could get their hands on. Other hospitals implemented conservation tactics, using replacements and alternatives when necessary and available, but a severe threat to the safety and quality of patient care still looms (Mazer-Amirshahi & Fox, 2018). In response to the shortage, hospitals throughout the country have adopted strategies to ensure patients were getting the medications and care while minimizing the use of IV bags. For instance Curt Passafume, VP for pharmacy services at OhioHealth, said, “We have gone into the aggressive shortage-management mode.” He continued, “I've never seen anything like this before. It's challenging us to think differently than we thought in the past, because we have to.

Given the small number of producers, this situation will not be resolved quickly. Most pharmaceutical companies have not shared detailed status about their products, potential shortages, or availability/release dates. Baxter is one of the few companies that we are aware of that has had contact with the FDA, which prompted the FDA to allow importation of small-volume IV solutions from Ireland and Australia (Mazer-Amirshahi & Fox, 2018; Scott Gottlieb, 2018). However, this importation met only 10–15% of hospital and health system demand (Mazer-Amirshahi & Fox, 2018).

Immediate action is needed to ensure patients can get the care they need. But beyond the immediate need to rectify the emergency, US government should examine how the pharmaceutical industry communicates information about what drugs are manufactured at which plants and where those plants are located. There is no state or federal law requires that this information is disclosed. This lack of transparency puts healthcare systems at a significant disadvantage when trying to take a proactive approach to handle a potential drug shortage (E. Fox, 2018). The current system results in a reactive approach, which is usually short-notice and has a rapid downstream effect, leaving hospitals at a loss to meet patient needs. Furthermore, the current pharmaceutical infrastructure allows for a significant number of manufacturers to be geographically located in an area that is at high risk for natural disasters.

**Conclusion**

Puerto Rico manufacturing plants are critical supplies of IV bags to hospitals which are used in most of treatments of diseases (Mazer-Amirshahi & Fox, 2018). Despite evidences of need, Baxter has no redundancy in manufacturing capacity for small-volume saline bags. The other two saline suppliers have not been able to increase their production enough to make up for the shortage (Langreth & Coons, 2017; Scott Gottlieb, 2018). Moreover, saline produced by one of the other suppliers was already in short supply before the hurricane, as the company worked to correct manufacturing-quality problems (Langreth & Coons, 2017).

Although critical, this episode of natural disaster is not new. Hurricane Georges in 1998, for example, was only a category 1 storm, but its path across the entirety of the island and its torrential rainfall make it one of the worst natural disasters in Puerto Rico’s history (Fritz, 2017). The hurricane caused no direct fatalities, but the damage to infrastructure was almost total.

A strong virus led to a lot of hospitalizations during the 2017-2018 flu season. However, we have enough evidence to believe that the fact that there was a massive problem in the IV-bags supply chain caused by the closure of plants in Puerto Rico during the Hurricane Maria, directly contributed to the high death rate of the 2017-2018
flu season. This sheds new light on how the US health care system should manage its supply chain risk and avoid costs to the system and to the society. The fact that so many critical medical and pharmaceutical components are sole produced in a single island with not enough infrastructure is concerning and, as seeing in the 2017-2017 flu season, can be life threatening. Given the possibility of new natural disasters, public managers need to rethink locations of pharmaceutical plants in addition to ensuring that backup systems can quickly accommodate needs in the event of a disaster.

Even without using the specific terms, the importance of looking at supply chain risks, had been acknowledged in a letter sent to congress and signed by the American Hospital Association, the American Society of Anesthesiologists, the American Society of Clinical Oncology, the American Society of Parenteral and Enteral Nutrition, and the Institute for Safe Medication Practices. In the letter, they raise six questions and call for a comprehensive strategy to manage drug shortages. All six questions are related to risk management in the supply chain (ASHP, 2018).

Many critically important medical products—which includes sophisticated drugs, biologics, and medical devices—are manufactured in Puerto Rico. The combination of a severe flu season and reduced supplies of intravenous (IV) fluid bags after Hurricane Maria devastated manufacturing plants in Puerto Rico put hospitals in critical situation. This event showed how the U.S. healthcare system can have a significant public health difficulty because the location of pharmaceutical plants. Even though manufacturing redundancies may not change the course of the current saline shortage, they are important actions for preventing future shortages, avoiding unwanted costs, and saving lives.

Abstract

Communities of Practice (CoPs) are increasingly being used to facilitate knowledge sharing across organisational and professional boundaries. This study aims to refine our understanding of processes of knowledge mobilisation in CoPs. It does so by describing identity reconciliation practices during the early stages of a mandated ‘CoP’ set up to mobilise process improvement knowledge in healthcare. Our findings reveal three modes of member engagement - ‘identification’, ‘distancing’, and ‘peripheral lurking’ - showing how meanings associated with a ‘CoP’ and the knowledge being mobilised may play a role in determining how members make sense of their identity in relation to CoPs.

Key words: Community of Practice, Healthcare, Knowledge Mobilisation

Introduction

Healthcare settings around the world are under pressure to increase efficiency whilst improving service quality and patient safety (Poksinska, 2010; Fillingham, 2007; Radnor & Johnston, 2012). One significant response to these pressures has been attempts by policy-makers, healthcare managers and some improvement-focussed clinicians, to promote the use of service redesign methods and techniques proven to be effective in other industries (e.g. Lean thinking and related approaches) (Ben-Tovim et al., 2008; Radnor & Boaden, 2008). However, attempts to mobilise externally derived redesign and process improvement knowledge in healthcare has faced many barriers and challenges associated with a somewhat more complex, multi-stakeholder setting and its associated organisational, occupational and professional boundaries (Kislov, 2018; McNulty & Ferlie, 2002; Oborn et al., 2013). These issues have led to a growing interest in promoting collaborative approaches to bring stakeholders together and to enable knowledge to mobilise across boundaries. One approach which has provided a focus of attention is the idea of 'Communities of Practice' (CoPs) (Li et al., 2009).

However, contradictory accounts of how CoPs form exist in the literature. In seminal works (E.g. Lave & Wenger 1991; Brown & Duguid, 1991), the concept was deployed as an analytic tool to understand social learning, identity-formation, meaning and practice in ‘organic’, uni-professional CoPs. In this view, CoPs must ‘emerge’ organically. In
more instrumental views, CoPs can and should be deliberately established to manage the flow of knowledge and to enhance knowledge-sharing (e.g. Wenger, McDermott & Snyder, 2002). Exploring the tensions between analytical and instrumental views of CoPs is of significant importance due to the growing popularity of promoting knowledge mobilisation through CoPs (Bunger & Lengnick-Hall, 2018; Ferlie et al., 2010). In particular, it raises the question of whether CoPs can in some way be ‘mandated’ in settings such as healthcare where collaboration is increasingly seen as central to knowledge mobilisation (Ferlie et al., 2012; Nicolini et al., 2016).

Drawing on the analytic approach to CoPs, we sought to investigate the processes by which actors negotiate their simultaneous membership in existing organic CoPs (e.g. professional disciplines) with their ‘membership’ in new, mandated ‘CoPs’. To do so, we undertook a longitudinal qualitative case study of the early stages (first 12 months) of a mandated multidisciplinary, multi-organisational ‘CoP’, established by policymakers with the aim of mobilising process improvement knowledge across the public healthcare system of an Australian jurisdiction.

The remainder of this paper progresses as follows: First, we define CoPs and discuss their instrumental use in healthcare, highlighting some of the empirical challenges. Next, we introduce our theoretical approach which draws on analytic perspectives of CoPs and focusses on identity reconciliation and related knowledge translation practices of actors. We then briefly outline the case and our methodological approach before presenting our findings in terms of 3 modes of engagement. Finally, we return to the literature in light of our findings and conclude with practical implications of our findings.

**Defining CoPs, and CoPs in healthcare**

Lave & Wenger (1991) coined the term ‘CoP’ in their situated theory of learning. The concept was used to show how newcomers are socialised into professions and crafts by learning how to be as much as what to do, through legitimate peripheral participation - ‘a continuous, active, engaged, situated and identity-forming process’ (Cox, 2005). In this view CoPs are highly institutionalised, and professionals automatically belong by virtue of being part of a specific discipline (e.g. doctors, nurses) (Ferlie et al., 2005). They are organic, emergent and cannot be purposefully formed by organisations (Kislov, 2012).

Notwithstanding the origins of CoPs as an analytical device, policy-makers and practitioners have embraced these ideas in more instrumental terms as a means of promoting knowledge sharing (Ferlie et al. 2010; Li et al., 2009). This is particularly so where attempts have been made to mobilise forms of knowledge from outside the sector, such as service redesign and process improvement knowledge (Nicolini et al., 2016).

However, bringing together actors with partially incompatible ‘epistemic cultures’ (Knorr-Cetina, 1999) is likely to result in members of mandated ‘CoPs’ facing sticky boundaries in their interactions with actors from other disciplines. Consequent processes of negotiation have implications for how knowledge is mobilised (Ferlie et al., 2010; Kislov et al., 2011; Kislov et al., 2012). In particular, previous research suggests that mobilising redesign and process improvement knowledge is likely to be most challenging in the case of clinicians, especially senior medical clinicians, as a result of strong professional boundaries, their dominant status and the potential for ‘epistemic clashes’ (Albert et al., 2008; McGivern & Dopson, 2010; McGivern et al., 2016).

While more recent studies have expanded our understanding of the processes involved in the formation of CoPs (e.g. Gabbay et al., 2003; Ferlie et al., 2005; Kislov et al., 2012; Kislov, 2013; Kislov, 2014), most studies of CoPs in healthcare have tended to be analysed in terms of the extent to which they facilitate their intended outcome - the smooth ‘transfer’ of knowledge (Li et al., 2009; Swan et al., 2016). Relatively little
empirical research has focussed on the specific processes that take place when multiprofessional, multi-organisational 'CoPs' are mandated (Kislov, 2012; Pyrko, Dorfler & Eden, 2017). Moreover, most studies of CoPs in healthcare have focussed on clinical rather than management knowledge (McGivern et al., 2016; Swan et al., 2016).

**Tracing translation practices**
Returning to the tradition of analytic perspectives on CoPs - with *practice* as the starting point, this paper takes the tools of the CoP approach, and practice studies more generally, as a useful lens through which to explore the knowledge translation practices actors engage in when brought together in a mandated multi-professional, multi-organisational ‘CoP’. This view assumes knowledge to be social, contextual and political and cannot be unproblematically ‘transferred’ among individuals (Swan et al., 2016). Instead, ideas are assumed to be transformed as they spread (Andersen & Røvik, 2015), and we are led to contemplate why different actors engage with certain forms of knowledge differently under different conditions (Duguid, 2005; Ferlie et al., 2005; Swan et al., 2016).

In Wenger’s (1998) account of learning as social participation, it is the negotiation of meanings and identities, in practice, that results in the formation of CoPs as locally negotiated ‘regimes of competence’ (p. 137). Viewed in social terms, identities are constantly formed and reformed through social participation – both a process of transforming knowledge, and a place where new ways of knowing are realised in the form of identity. Becoming a CoP member means taking on an identity, and negotiating it through practice, with others.

Competent membership in a CoP involves: 1) the ability to *mutually engage* with other members in interaction that leads to shared meanings, 2) the ability to understand and take responsibility for negotiating the community’s *joint enterprise*, and 3) the ability to make use of the community’s *shared repertoire* of common resources and language to engage in, and therefore negotiate, practice (Wenger, 1998). To become even a peripheral member, one must be both *able and willing* to engage with all three dimensions.

However, politics of participation exist, and the negotiated experience of the self in the context of a ‘nexus of multi-membership’ in various CoPs involves complex ‘reconciliation work’, necessary to maintain a livable identity across boundaries (Wenger, 1998). Despite its significance, identity reconciliation happens privately, may not be consciously acknowledged, and is rarely viewed as part of a CoP’s enterprise. Thus, it usually remains hidden (Wenger, 1998, 2010) and has rarely been investigated.

Yet processes of identity reconciliation are likely to have significant implications for how knowledge is translated across boundaries. In the healthcare context, with its strong pre-existing professional and epistemic boundaries and complex broader structures of knowledge and power, this ‘reconciliation work’ is likely to be especially challenging for actors. In particular, clinicians must negotiate their way through a transition which allows them to reconcile their pre-existing clinical identity (in the case of senior medical clinicians, strongly associated with status, autonomy and a host of deeply-held assumptions about care and best practice) with a new non-clinical identity, and maintain both simultaneously. This transition has implications for how knowledge is mobilised and translated in the process (e.g. McGivern et al, 2015), and is likely especially challenging when a ‘CoP’ is mandated to facilitate the ability of a ‘non-profession’ (process improvement practitioners) to mobilise ‘outside’ knowledge and incorporate it into the practice of dominant professional players.

**Research design and methods**
A longitudinal case study methodology was employed to follow in real-time the ‘setting up’ of a multi-professional and multi-organisational knowledge mobilisation initiative -
henceforth the 'Emergency CoP’. The CoP was the brainchild of policymakers responsible for healthcare innovation and improvement in the public system of an Australian jurisdiction in which process improvement had been promoted over a number of years, and a cadre of funded and trained improvement practitioners was active within individual health service organisations. In the face of problems spreading and scaling process improvement knowledge, policymakers sought ways to encourage cross-organisational learning with an initial focus on improving access and flow in emergency care.

To this end, the jurisdiction provided administrative support for 12 months, established an online forum, and funded one consultative and three substantive workshops. Policymakers chose improvement practitioners as their primary point of contact with health services, some of whose roles were either currently being funded or had previously been funded by the jurisdiction. They were encouraged to attend alongside frontline clinical staff selected by participating healthcare organisations, mostly ED clinicians from medical and nursing disciplines, usually with some level of managerial responsibility and an interest in the application of process improvement knowledge. Thus, the mandated CoP brought together two types of actor: ‘improvement practitioners’ with specific responsibility for and expertise in process improvement and ‘improvement-oriented clinicians’.

We undertook a qualitative case study which facilitated our exploration of how improvement practitioners and improvement-oriented clinicians worked to reconcile their existing identities with ‘membership’ in the Emergency CoP, and how in the process they understood, negotiated and translated the service redesign and process improvement knowledge the policymakers aimed to mobilise. Nineteen semi-structured interviews (7 clinicians, 12 improvement practitioners), and observation of the four workshops between May and December 2018 allowed “doings and sayings” (practices) (Nicolini & Monteiro, 2017, p 110) to be captured. We outline our findings under the headings ‘identification practices’, distancing practices’, and ‘peripheral lurking practices’.

**Findings**

**Identification Practices**

Improvement practitioners who were new to the overall program in the sector or new to improvement roles, and nurses in hybrid nursing/management roles (E.g. Nurse Unit Managers), were most ‘hungry’ for both the knowledge content and the contacts that participation in the Emergency CoP provided. This group easily reconciled their existing identities with their new membership in the Emergency CoP. In terms of reconciliation practices, they undertook the following. First, they emphasised the lack of community related to process improvement within their home organisations:

*If there is anything in the hospital where it's a big meeting for change, I don't know about it. It's not a thing. Maybe that's what government need to mandate. You need to have a department to specifically focus on improvement strategies, pathways, flow. (Participant 9, ANUM)*

*It's hard to imagine, to rewind two years ago prior to all this collaboration, I can't imagine what it would have been like to work at [my health service] without all of this. Actually, I can imagine because I did spend four months here in 2016, 2015 doing an internship project. (Participant 24, improvement practitioner)*

Secondly, they easily articulated the benefits of the CoP and their desire to belong:

*I think for me the biggest benefit has been getting to meet my counterparts in all of the other organisations, and then hearing... Yeah just having the opportunity to look*
around and see what everyone’s doing, what’s working, what problems are they facing (Participant 24, improvement practitioner)

That’s exactly what this is all about. We can learn from each other… The initiative is fantastic, by the way… and I will be involved with it from here on, I can tell you that. (Participant 9, ANUM)

Finally, they sought to identify with the policymakers’ brand, as this had perceived benefits for their own practice of improvement within their organisations:

Maybe I’m wrong but I think that having [the jurisdiction] behind it lends more credence. So therefore other people listen to it more… if we wanted to start this… to get our flow going, having it under the umbrella of [the jurisdiction] gives it more credence. So we can say, "This has come from [the jurisdiction], not from me, not from anywhere else." (Participant 18, NUM)

**Distancing Practices**

Many improvement practitioners in the CoP had been in the improvement game for an extended period, either as veterans of the jurisdiction’s own capability-building program or in outside industries prior to moving into healthcare. They were highly experienced service redesign and process improvement practitioners. Counter-intuitively, this group had the most difficulty reconciling their existing identities as improvement experts with their membership in the new Emergency CoP. This played out in the following ways. First, while they attended CoP meetings and contributed to discussion, ‘backstage’ they emphasised their membership in existing CoPs of improvement practitioners:

Well, I knew [improvement practitioner from another health service] from my time at department, but … I don’t know that that’s just because of that. I think I would have known [him] anyway. I think there’s maybe like a mutual respect. I respect that they’re doing something. They respect that we’re doing something and that forces us to talk. I’ve got the same relationship with [improvement practitioner at another health service]. Same relationship with [improvement practitioner]. (Participant 27, improvement practitioner)

They also described these existing CoPs as where the ‘real’ knowledge mobilisation happens, ‘backstage’ of the Emergency CoP and its formal meetings:

And I was comfortable to say, "I have no idea mate, but I'll try and find out for you." And then my boss and [colleague] were comfortable just to have a chat to [colleague at another health service] over the phone. That's the real Community of Practice. (Participant 27, improvement practitioner)

Second, this group felt under pressure from policymakers. For them, involvement in the Emergency CoP was yet another obligation over which they had little choice:

I am feeling more and more owned and directed by them in a way that’s not necessarily of any benefit to me. It's gone from having no interest three years ago and no direction and support to almost, the pendulum swung way too far. Way, way too far… and I think there’s more and more of my role in the sector who are feeling exactly the same way... Under pressure and being micromanaged. (Participant 11, improvement practitioner)
Furthermore, they interpreted policymakers’ activities as concerned with achieving their own targets rather than genuinely helping to facilitate knowledge mobilisation:

*My impression is that they're very KPI driven... it sounds like there's KPIs regarding how many workshops they hold and how many times people go on [the online forum].* (Participant 12, improvement practitioner)

Finally, the ‘distancing’ engaged in by these improvement practitioners involved simultaneously diminishing the value of the CoP for themselves as competent improvement professionals, and promoting the value of the knowledge for others:

*I just don't think it should be geared at me. It needs to be geared at people at the ground... heavily involved in that practice. Because I've heard that guy from [health service] speak several times before. Like I've heard it all before.* (Participant 10, improvement practitioner)

**Peripheral Lurking Practices**

Policymakers expected that senior medical clinicians would be the most difficult to engage. Our findings show, however, that like the improvement veterans, senior clinicians also engaged in contradictory ‘frontstage’ performances of engagement and ‘backstage’ distancing. However, our data suggest the underlying motivations of these clinicians differed. In terms of negotiating their existing identities with their membership in the Emergency CoP, they worked to preserve their clinical identities and simultaneously maintain a position as genuinely interested participants in the CoP.

First, whereas the ‘veteran’ improvement practitioners regarded the increasing levels of improvement activity organised by policymakers to be a hindrance, senior doctors publicly identified with the policymakers’ endeavours to mobilise process improvement knowledge in the hope it would improve the operational efficiency of the busy emergency departments they struggled in day to day:

*Comparing 5 years ago to today, arriving at work is very different. It feels like we are all in it together.* (Senior ED doctor, quoted in field)

Furthermore, while improvement practitioners had ‘heard it all before’, senior doctors valued the opportunity to hear what was happening in other services and engage with policymakers:

*It was interesting to hear how much variability there was and how frustrating it was ... and a lot of people saying what we really want from the Department of Health is to say "This is the requirement, so do it."* (Participant 19, senior doctor)

Second, while ‘veteran’ improvement practitioners justified disinterest in the CoP by highlighting their existing expertise and involvement in a community of experts, senior doctors sought to maintain distance from process improvement in their everyday practice:

*I think I still haven't really got the hang of PDSA cycles and quality improvement processes and so forth and I'll leave it to others probably. I was going to appoint someone else to run those projects.* (Participant 19, senior doctor)

Finally, while senior doctors attended the CoP and engaged actively, ‘backstage’ they sought to maintain their distance from other disciplinary groups:

*In the CoP when I'm asking for advice... sometimes how things are phrased at the exec level is not work as done, they've misinterpreted, or how they imagine how my job...*
works isn't quite correct. So if I know I'm talking to someone on the shop floor... it adds a bit more authenticity to the advice. (Participant 4, senior doctor)

Discussion
As we have outlined, research to date suggests that mobilising improvement knowledge in healthcare is likely to be most challenging when changes to clinicians’ practice are at stake (Currie, Kotevyko & Nerlich, 2009; Jorm, 2016; Radnor et al., 2012), especially during top-down intervention (Waring & Currie, 2009). This has been attributed to strong professional boundaries, their dominant status and the potential for ‘epistemic clashes’ with this outside knowledge and its proponents (Albert et al., 2008; McGivern & Dopson, 2010; McGivern et al., 2016).

In contrast, we found that it was improvement practitioners with ‘veteran’ experience were the least genuinely engaged in attempting to further mobilise improvement knowledge through a mandated CoP. Less counter-intuitively, improvement ‘novices’ (newer improvement practitioners and lower status improvement-oriented clinicians) tended to be highly engaged and able to reconcile membership in the Emergency CoP with their existing identities, and no dissonance was observed in their ‘frontstage’ and ‘backstage’ performances of ‘identification practices’. In contrast, the ‘distancing practices’ of improvement ‘veterans’ and ‘peripheral lurking practices’ of senior doctors were both marked by significant differences in what was said and done within the public forums of the CoP, and what was said and done outwit of this mandated community. We suggest that this pattern can be explained as follows:

First, those relatively new to the world of healthcare improvement were most likely to seek mutual engagement with others on the joint enterprise of improving access and flow in emergency departments, and to willingly be part of developing the shared repertoire of the ‘CoP’ (Wenger, 1998). As process improvement knowledge suffers legitimacy issues in healthcare, 'CoPs' mandated at the jurisdiction level could be expected to bolster the legitimacy of this type of knowledge and practice, and thus the ‘subject position’ of those who practice it (Lockett et al., 2012). For improvement novices and lower status clinicians, this top-down support provided them an entry point into the ‘regime of competence’ of process improvement that they otherwise had little ability to access and negotiate (Wenger, 1998).

As a result, improvement novices emerged as a sub-community for whom the invitation to participate in the ‘CoP’ was a clear opportunity - a perceived window to legitimate peripheral participation (Lave & Wenger, 1991) and an identity which was easily reconciled with their existing one, and would bring them a shared future with those they considered “leaders in the field” (Participant 22, ANUM) (Wenger, 1998; Wenger, 2000). Their identification practices set them on an ‘inbound’ trajectory (Wenger, 1998, p. 154), because the prospect of fuller participation represented a valued future identity. As such, their ‘public performances’ and ‘backstage’ accounts were consistent. These already ‘willing’ participants felt they would be made more ‘able’ to practice service redesign and process improvement by belonging to the Emergency CoP.

Second, and by contrast, the improvement ‘veterans’ displayed a contradictory and unexpected set of distancing practices. As was the case with improvement novices, the kind of knowledge being mobilised fit their ‘epistemic culture’ (Knorr-Cetina, 1999; McGivern et al., 2016). We could expect that support from the jurisdiction in the form of direct ‘mandated’ support for this type of practice, and the jurisdiction’s concerted effort to engage medical clinicians, would make their core day to day work of knowledge brokering easier by also enhancing their ‘subject position’ and legitimacy (Lockett et al., 2012). We might also expect that they would automatically form the core of the emerging
‘CoP’ as ‘masters’ of the practice, and be enthusiastic about socialising newcomers into it (Lave & Wenger, 1991).

However, the ‘veterans’ diminished the learning value of the Emergency CoP for themselves. They were already the generators and custodians of the ‘tacit dimensions’ of process improvement knowledge - accordingly, they asserted that they had ‘heard it all before’ and promoted the value of participation in the Emergency CoP for less experienced ‘others’ - constructing their own ‘expert’ identity at the boundary with non-experts (Jenkins, 2000; Lamont & Molnar, 2002). This could be interpreted as an assertion of their jurisdictional claim to ownership over improvement expertise, and therefore epistemic authority (e.g. Kislov, 2014). Furthermore, in the Emergency CoP, the ‘ownership of meaning’ and thus the ability to negotiate the regime of practice, its meanings, and their position within it was concentrated with the policymakers who the ‘veterans’ already felt wished to exert control over them. Thus, in negotiating a coherent identity that could incorporate this mandated ‘CoP’ within their existing ‘nexus of multi-membership’ in other CoPs, their identity reconciliation work appeared to set them on an ‘outbound trajectory’ (Wenger, 1998, pp. 155). While policymakers hoped that the CoP might improve this group’s ability to broker their expert knowledge, the ‘mandated’ nature of the CoP made improvement practitioners less willing to engage in this practice in this setting.

Third, senior medical clinicians were expected by policymakers to be the most challenging group to engage with service redesign and improvement knowledge, but they were surprised at the apparent level of clinical engagement in the Emergency CoP. Despite this, we found that, like the ‘veterans’, senior clinicians also undertook contradictory ‘public’ engagement and ‘backstage’ distancing, unseen by the policymakers. Publicly, senior clinicians presented a ‘unified front’ with their organisations’ improvement team - in itself, unsurprising given that clinicians attending the Emergency CoP were likely open to external ideas. However, they took their ‘epistemic stances’ (McGivern et al., 2016) backstage. Here, they enacted their attitudes toward management knowledge and practice, and displayed their conviction (and justifications for it) that these were not worthwhile engaging with and developing (McGivern et al., 2016).

The central proposition of Lave and Wenger’s (1991) theory of situated learning and legitimate peripheral participation is that learning is about identity change; through peripheral participation, one learns to be a member and to participate in a social activity system, which involves being able to mobilise and translate knowledge in ways that make sense to others in that system. Rather than seeking an inbound trajectory to full participation through identification practices as the improvement ‘novices' did, or an outbound trajectory through distancing practices as the improvement ‘veterans’ did in their quest for epistemic authority and autonomy, the senior doctors in this study sought a ‘peripheral trajectory’; to maintain their professional autonomy and epistemic boundaries by lurking at the periphery (Wenger, 1998, p. 154). As others have found, ‘efficiency’ discourses implicitly challenge professional discourses, since integrating them potentially allies professionals to managers and in this case, policy-makers (Sanders & Harrison 2008). This has the potential to undermine the traditional autonomy of the medical profession (Cox, 1991; Dent, 1993). Maintaining a peripheral position enabled them to participate in the CoP and keep a finger on the pulse with regard to policymakers’ intentions concerning the improvement of emergency care across the jurisdiction, and at the same time protect their highly valued professional autonomy.
**Conclusion**

Drawing on the analytical CoP approach, we have brought into focus the private and usually hidden work of meaning-making and identity reconciliation, and politics of practice (Wenger, 1998; Nicolini, 2009). We have shown that the meanings different participants attribute to a mandated ‘CoP’ and the type of knowledge it aims to mobilise may play a key part in determining their modes of engagement, and ‘inbound’, ‘outbound’ or ‘peripheral’ trajectories (Wenger, 1998). Future research might focus on refining the modes of engagement suggested in this study and exploring others (for example using Wenger’s (1998) other trajectory types – ‘insider’ and ‘boundary’).

In conclusion, if CoPs are to be created to enhance knowledge mobilisation, an element of ‘mandatedness’ is inescapable. However, the risks associated with formalising knowledge mobilisation may be offset if those who create them anticipate the politics of participation that will inevitably emerge as people work to reconcile their existence in a ‘nexus of multi-membership’ in various CoPs.

Abstract

Service integration is considered essential in order to provide efficient and customer oriented health and social services. However, particularly inter-organizational integration is found to be challenging due to e.g. the diverse aims of different organizations. Interfaces in modularity are elements that ensure fluent compatibility of service components and collaboration between people. The aim of this study is to analyze whether interfaces can support the inter-organizational integration. Interviews were conducted from the service process for Down syndrome children in the Netherlands and elderly care from Finland. Although, inter-organizational interfaces were found, they seem to be scant and problematic.

Keywords: Integration, Interfaces, Healthcare

Introduction

Development requirements in healthcare are increasing due to the e.g. decline of public economy and customers’ rising expectations. The public sector has been accused of being fragmented (Kodner, 2009) and thus inefficient (Nolte et al., 2012). In order to provide value for money, healthcare providers are expected to increase the cost effectiveness of their services. Furthermore, customers are increasingly expecting more customer orientation and patient-centered care (Singer et al., 2011). One solution to decrease inefficiency and enhance customer orientation is argued to be service integration. Despite
the consensus that service integration supports e.g. effective use of resources, high quality outcome and patient satisfaction (Berwick et al., 2008; Suter et al., 2009), service integration has been challenging to achieve in practice (Busetto et al., 2016; Kodner, 2009). This has been particularly the case for complex health problems in which services are produced over longer period of time by multiple providers from different organizations.

Modularity has the potential to support integration as it is said to bring better manageability, and thus better efficiency to complex systems (Bask et al., 2010). From the customer perspective, modularity is said to bring variety and possibility to flexibly combine customized service packages (Pekkarinen & Ulkuniemi, 2008). Interfaces in modularity are key elements to enable flexible compatibility of components (Bask et al., 2010; De Blok et al., 2014). The extant literature does describe some classifications for framing interfaces (see e.g. De Blok et al., 2014; Broekhuis et al., 2017; Spring & Santos, 2014) while the literature still remains scarce. For example, the inter-organizational challenges related to interfaces, pointed out by Vähätalo (2012), continue to be a rather unexploited perspective (Peters et al., 2018a). Thus, more research is needed to recognize and analyze interfaces in inter-organizational settings as well as to analyze whether interfaces can alleviate the challenges of fragmented services and support service integration.

In our paper, we build on the work of de Blok et al. (2014). Moreover, we bring the inter-organizational perspective in the interface discourse in the healthcare setting. We base our empirical findings in data collected from Down syndrome care in Netherlands and homecare for elderly in Finland.

**Theoretical background**

*Interfaces in service modularity*

The concept of modularity and our understanding of modules can be underpinned thought three design principles, namely 1) specific function, 2) relative independence, and 3) standardized interfaces (e.g. Rajahonka et al., 2013; Peters et al., 2018a). Since services are mostly consumed over a longer period of time and customers’ needs and requirements might change frequently (Voss & Hsuan, 2009) it is important to enable rearrangement of services. Interfaces have an important role in compatibility of modules and (re)configuring the service. Because the main focus of this study lies upon health services, we use the definition of interfaces provided by De Blok et al. (2014). They defined interfaces as: “The set of rules and guidelines governing the flexible arrangement, interconnections, and interdependence of service components and service providers” (p. 186).

Although the literature concerning interfaces is scarce, some classifications can be recognized from the extant literature (Peters et al., 2018a) e.g. Broekhuis et al.’s (2017) and Spring and Santos (2014). The most comprehensive classification is presented by De Blok et al. (2014) and applied, for example, by Soffers et al. (2014). The typology by De Blok et al. (2014) is based on two dimensions, interface entity and interface aim. The interface entity refers to the decomposition level – components and services providers – while the interface aim can be either providing coherence or variance (De Blok et al. 2014). Broekhuis et al. (2017) go one step further and point out the way in which the interface design process is affected by the heterogeneous nature of different disciplines and professions they represent. However, the inter-organizational perspective remains unexploited in these studies. Furthermore, there is no studies analysing what possible links exists between the concepts of healthcare integration and interfaces described in operation management literature.
Integrated patient care

Social and health services have been accused of being fragmented (Nolte et al., 2012). Fragmentation causes ineffectiveness, and thus expenses resulting in low customer satisfaction and low outcome quality (Kodner, 2009). Integration of services is often put forward as the opposite of service fragmentation (see WHO 2016). Depending on the discourse and discipline, integrated services can be called synonymously as seamless care or coordinated care, among others (WHO, 2016; Zonneveld et al., 2018). Similarly, there are multiple definitions for integrated care depending on the context and purpose of the studies (WHO, 2016; Singer et al., 2011; Kodner, 2009; Kodner & Spreeuwenberg, 2002). Since we address the fact that health services are typically produced by multiple providers over a long period of time, we follow Singer et al. (2011) and define that in integrated services, patient care should be “coordinated across professionals and facilities, tailored to the patients’ needs and preferences and based on a shared responsibility between patient and caregivers for optimizing health continuous over time” (p. 113).

The extant literature recognizes integration at different levels. For example, Valentijn et al. (2013) identify integration at system, organizational, professional and clinical level. The extant literature reports challenges at different levels. For example, challenges related to divergent organization culture (Kodner & Spreeuwenberg, 2002), bureaucratic structures, funding mechanisms (Browne et al., 2004), information transfer (Manser et al., 2010) and contractual relations (Valentijn et al., 2013) can complicate the integration at organization level, whereas challenges at the professional level are likely to be related to lack of shared language and divergent healing paradigms (Valentijn et al. 2013; see also Broekhuis et al., 2017). Care processes in complex health problems typically consist of professionals from different disciplines representing different organizations (Valentijn et al., 2013). To conclude, not only professional but also organizational related challenges complicate the service integration in complex care settings.

Interfaces in integrated patient care

This section creates a conceptual synthesis and explicates the link between the definition of integrated care (Singer et al., 2011) with the interface typology presented by De Blok et al. (2014) (table 1). In doing so, we address the theoretical linkage between these two discourses and create a background for our empirical data analysis.

Coordination across professionals and facilities. According to Singer et al.’s (2011) coordination refers to the interaction across professionals or across organizations with the aim to deliver consistent and informed patient care. They mention that the coordination of care often seeks to achieve automation, efficiency and simplicity. Moreover, coordination aims to deliver consistent and informed care (Singer et al., 2011). This definition brings coordination close to the concepts of coherence applied by De Blok et al. (2014). Based on Singer et al.’s (2011) definition of coordination and the interface types introduced by De Blok et al. (2014), a link towards two types of interfaces can be recognized: C-I interfaces and C-C interfaces. C-I interfaces are interfaces that support coherence and unity among people (De Blok, 2010), while C-C interfaces support coherence in a service package among components (De Blok, 2010). Both types of interfaces diminish the amount of information exchanges needed, since the interactions between people or components can be prescribed via these types of interfaces (De Blok, 2010). Based on the ability of both interface types to provide predictability and coherence a link towards coordination can be recognized.
Tailored to the patients’ needs and preferences. Tailored to the patients’ needs and preferences’ is supported by a good communication between the service provider and the patient (AHRQ, 2011). Taking the patient’s preferences into account refers to personalization (De Blok et al., 2013) of the services and thus describes the process of the services. When a good relationship can be developed or is built the assessment level linked to customer needs and requirements will increase, which could effectuate customization (De Blok et al., 2013). An interface type that can support this process is an O-I interface, since these interfaces allows for the recognition of (changes in) patients’ needs and makes requirements possible (De Blok et al., 2014).

Shared responsibility between patient and caregivers for optimizing health. Shared responsibility can be supported by O-C interfaces (Peters et al., 2018a). A service provider together with, for instance a customer, may indicate some desired changes. When the desired changes are indicated, O-C interfaces can support this adaption process, since these interfaces provide a structure that enables the combination and recombination of component variations (De Blok, 2010). In the end, this structure can support the extent to which the customer, his/her family members, and other caregivers are obtaining information and are involved in, for instance, making healthcare decisions.

It can be concluded that more research is needed to recognize and analyze interfaces in inter-organizational setting in health and social services as well as to analyze whether interfaces can alleviate the challenges of fragmented services and support their integration. Our study builds on the comprehensive conceptualization by De Blok et al. (2014), and supports the work of Peters et al. (2018b) to address the inter-organizational perspective with regard to interfaces in service modularity. Therefore, the research questions are as follows:

1. How can we describe the interfaces in the provision of multidisciplinary care context?
2. How can interfaces be improved in order to support service inter-organizational integration of services?

Methodology
This study examines interfaces in two different case contexts, home care for elderly (Finland) and children with complex disease, Down Syndrome, (Netherlands). Data is collected by interviewing multidisciplinary teams/networks (i.e. public, private and NGO providers) operating in these contexts as well as the end users. The data from Netherlands (N=15) was collected during 2018 and from Finland (N=20) spring 2019. Due to the scheduling, only tentative findings from comparative analysis is presented. Comparative case study provides wide perspective to interfaces in diverse contexts and different service systems.

A semi-structured interview approach was applied which enabled a combination of addressing topics that have to be covered while leaving room for respondents to tell their
own story (Boeije, 2006). The interviews were based on the theoretical framework of this research. First, network analysis was conducted based on the interviews. Second, deductive content analysis were used to identify de Blok et al.’s (2014) classification and third, data were analysed to find suggestions to improve integration.

**Results**

**Interfaces**

We present results of the multidisciplinary healthcare provision for children with DS in the Netherlands and elderly care from Finland. Implicitly, we take a modular perspective and build on previous research in this context (Peters et al., 2018b). Various examples of interfaces were recognized and, as mentioned in the theoretical background section, we classify them according to the typology developed by de Blok et al. (2014) (Table 2).

To illustrate the interfaces found from DS and home care for elderly and to illustrate the table 2, we next provide some examples.

Closed-customer interfaces (coordination across the facilities). In Down Syndrome care C-C interfaces enable the arrangement of components, to ensure that components work together in a predictable way and overall coordination of services is covered. The planning scheme leading to a convenient order of the modules and the consultation scheme for a particular day are clear examples of C-C interfaces. These schedules are structured in such a way that a continuous flow of patient is created by matching the agreements of the various healthcare professionals involved: “For the eye drops to kick in, it takes about three quarters of an hour. In the meanwhile, another member could provide his consultation, making sure that the patient doesn’t have to wait” (Ophthalmologist). This ensures that the patient ‘flows’ smoothly through the system.

In elderly home care customers’ had an individual care plan that guided the care. Care plan was highly structured and well established among public provider and less so among private and NGO providers. Public providers also had process descriptions that concerned all home care teams in the city. These C-C interfaces aimed for standardization and predictability of care.

Open-information interfaces (Tailored to patients’ needs and preferences). O-I interfaces create a structure so that the healthcare professionals are brought together. The multidisciplinary team meeting serves as an example of this type of interface, as it allows the professionals to discuss the outcomes of their individual consultations. The gathered information of all the disciplines involved is discussed and leads to a joint outcome. Moreover, O-I interfaces were identified by means of the request for help that is asked at the start of every consultation: “I naturally start asking how things are going and if there are any questions” [Pediatrician]. Within the elderly home care multidisciplinary team meetings were organized typically within public providers. Information transfer was mainly organized via EPR within public provider and by phone calls across the organizations.

Inter-organizational integration

We recognized and analyzed interfaces in an inter-organizational setting in health and social services. Our empirics show that interfaces were at play at different levels: 1) between providers within the same organization (intra-organizational) and 2) between providers across organizations (inter-organizational) and 3) interaction between providers and customers. Despite the importance of interfaces between providers within the same organization as well as interfaces between providers and customers introduced e.g. by Springer and Santos (2014), we focused on integration between providers across organizations and the interfaces related to it. Next, we will elaborate examples of challenges related coherence and variety of services across organizations and how these challenges influence integration.

Integration between professionals from different organization refers to the interaction between service providers across organizations in order to deliver consistent and informed patient care. In this setting, it is especially of importance to focus on retrieval and exchange of information, as this is often lacking (Dobrzykowski and Tarafdar, 2015). The respondents of our study mentioned a number of situations were inter-organizational integration were jeopardized by poor collaboration and information transfer. We
classified these situations under the typology of De Blok et al (2014) and pointed out interfaces that could possibly enhance the integration of services (Table 3).

**Improvements linked to the coordination between professionals from different organizations.** Inter-organizational interfaces recognized in this study were, for example, achieved by means of face-to-face contact, a formal letter, mail contact, or a phone call. First, a C-I interface like mail contact is applied between the pediatrician and general practitioner (GP), when information is necessary about the medical history of the patient. Hence, this information is not readily accessible, since the EPF of the GP is not accessible for the pediatrician. One way of addressing this is by means of delivering the service by the same service provider, each and every time. We identified this as a C-I interface. This interface leads to a continuous caring relationship between a service provider and a patient. It can be achieved by concentrating the yearly consultation in the hands of preferably one or a few service providers. Due to this concentration, a service provider can be more effective in managing the chronic and complex conditions and monitor the (long-term) development of the patient (Cabana & Lee, 2004). In the end, this will lead to more familiarity with the medical history of the patient.

Similar challenge related to medical history occurred in elderly care where only public sector providers had access to EPF. Private providers or voluntary workers had no access to medical history. Furthermore, inside the public sector data entered by social workers was classified and not accessible for healthcare workers.

**Improvements linked to tailoring services according to patients’ preferences.** Related to DS case the interactions between the service providers of the multidisciplinary team and the service providers from primary care (e.g. physiotherapist, speech therapist) was considered poor. However, by means of the creation of an O-I interface, a situation can be created in which the needs, preferences, and capabilities of the patient are known prior to the consultation in DS case. Communication tools such as email formats can constitute these O-I interfaces. Although for this type of exchange of information, a secure transfer of information is compulsory and no specific consent from parents is required. This is based on the main rule of the Medical Treatment Contracts Act (WGBO) in the Netherlands: “Doctors must have permission from the patient for providing information to third parties. This explicit permission does not apply to care providers who are directly involved in the execution of the treatment agreement. They may receive relevant information from the treating physician with the patient's 'supposed consent'” (KNMG, 2018). If these interfaces are arranged, more stable and well-arranged communication lines can be achieved. In elderly care all providers were mainly responsible for re-configuring the services package of their own while the coordination of entire service entity was elderly’s duty. If changes in customers’ needs were detected by provider (that weren’t related to provider’s own service) it was on provider’s to consider whether they informed other providers. Furthermore, formal care plans were conducted particularly by home care providers from public sector. These care plans were not, however, communicated e.g. with third sector provider who organized day care for elderly once or twice a week. Thus there were missing goal-orientation across the providers.

**Improvements linked to the coordination between services offered by different organizations.** Based on the analysis it seemed that interactions between service providers take place on the basis of professionals’ work experiences, but not substantively on the basis of protocols or guidelines. As a result, service providers have expectations about obtaining certain information of other service providers that is incorrect. This can lead to incomplete information. Therefore, it should be clear what every service provider is doing, when he is doing it and why is doing it. One way of addressing this issue is incorporating planning rules and planning schemes (C-C interfaces) among service
providers. In elderly care service description were not shared across the organization and thus overlapping and confusion about service content occurred.

**Improvements linked to shared responsibility.** With regard to O-C interfaces, a situation exists where interactions between healthcare professionals take place on the basis of professionals’ work experience, but not substantively on the basis of a clear C-C interface. This shows that professionals can have expectations about obtaining certain information of other professionals that are incorrect: “You are not aware of the kind of activities that other disciplines perform” [ENT-doctor]. Next, there is little interaction between the members of the DS multidisciplinary team and the specialists from primary care (e.g. physiotherapist, speech therapist). This could lead to situations where the needs, preferences, and capabilities of the patient are unknown prior to the consultation. Both the healthcare professionals as well as parents express this: “There is actually no contact between our own speech therapist and the speech therapist of the Downteam. When we visit the various disciplines of the Downteam, we have to explain what our own speech therapist is working on” [Parent] and “I often only hear during the consultation whether the child has had speech therapy and if there is any possible information available from this speech therapist” [Speech therapist]. If the medical history is known in advance, healthcare professionals are able to prepare their consultation even better. In elderly care providers had not enough knowledge about services available. For example, loneliness was a common challenge among elderly while care workers had not knowledge about all the services alleviating loneliness.

| O-C       | Poor variability of services/Not enough information about providers and their services available  
Missing service architecture | • List of providers and their services available  
• The provision of a service architecture in which the modules |
Conclusion
Based on our findings, we assume that interfaces can enhance integration on three levels: integration between professionals within the same organization (intra-organizational), integration between professionals from different organizations (inter-organizational). Although the typology by de Blok et al. (2014) provided a useful framework to scrutinize the interfaces in healthcare, it does not entirely capture the different levels that are in play in the type of health and social services that we were examining. In this study, we mainly concentrated on inter-organizational challenges which seem to be more severe than others. We point out that by improving inter-organizational interfaces, integration in healthcare can be improved.

Barriers to integration at service provider levels are recognized previously e.g. by Valentijn et al. (2013). Similarly, challenges related to interface design process are studied by Broekhuis et al. (2017). However, based on the results of this study, additional challenges in integration are likely to occur if providers represent different organization. This finding is in line with previous studies (Valentijn et al., 2013), who reported challenges in integration related to inter-organizational settings. Since most care paths cross organizational boundaries, it is important to study inter-organizational integration and how it can be improved.

Similarly as in previous studies, we recognized interfaces related to components and providers (e.g. de Blok et al., 2014; Spring and Santos, 2014). However, unlike previous studies we argue that, simultaneously, interfaces can be separated to exist both within and across organizations. This study bridged two discourses from different disciplines, namely integrated care and interfaces as a part of the service architecture. We pointed out the connection and the way in which well-defined interfaces can support service integration. Inter-organizational interfaces have the potential to support not only efficiency of the service process, but also customer orientation of the services.

In inter-organizational settings, coordination of service providers and service components is challenging (Dobrzykowski & Tarafdar, 2015) as the number of components is relatively high and responsibilities are shared between several autonomous providers. Furthermore, different organizations might have e.g. different resources and practices (Valentijn et al., 2013). Therefore, as a practical contribution we suggest to pay attention to inter-organizational interfaces in order to enhance the integration at the organizational level. To conclude, we suggest that interfaces can be seen as means to improve inter-organizational integration in the context of complex services.

Inter-firm relationships in supply chains in health care.
Evidence from an extensive survey

Keywords: Satisfaction; Mediation model; Health care supply chain

Topics: Healthcare Operations Management; Managing Inter-firm Relationships in Supply Chains; Operations in the Public Sector

Word count: 995

Purpose
Improving hospital supply chain performance has become increasingly important to improve operational efficiency and to reduce cost, particularly in public systems. Hospital supply chains are unique and different from the typical industrial supply chains in many aspects; nonetheless there is still a lack of theories developed with specific considerations of this sector (Chen et al 2013). This paper aims to investigate SC inter-organizational relationship, identifying the determinants that mostly impacting on customer satisfaction in health care.

Research design and methodology
Literature deeply investigated the link between relationship quality, that is a relational outcome and an overall means of assessing the strength of a relationship between two firms (Caceres and Paparoidamis (2007)), and service quality. In particular, relationship quality may be influenced by service quality, even though service quality can be considered a necessary but not sufficient, condition for relationship quality (Crosby 1990). Given this premise, the first hypothesis tested is the following:

H1: Service quality has a positive impact on relationship quality.

A great body of literature has focused on the determinants of customer satisfaction, and in particular, some scholars have analysed the relationship between service quality and customer satisfaction (Caceres and Paparoidamis (2007)). Although this relationship has been investigated in both directions, the majority of findings showed how service quality can be considered as an antecedent of customer satisfaction (Dick and Basu (1994); Cronin and Taylor (1992)). In fact, [...] quality is one dimension on which satisfaction is based (Rust and Oliver, 2000). Therefore, our second hypothesis is the following:

H2: Service quality has a positive impact on overall customer satisfaction.

Wulf et al. (2001) suggested how an improvement in relationship quality generates a higher level of satisfaction, trust, and commitment. Therefore, considering the first two hypotheses
and the potential impact of relationship quality on overall customer satisfaction, we propose the following third hypothesis:

**H3**: Overall customer satisfaction is influenced by service quality and relationship quality, even though relationship quality plays the main role.

The analysis has been performed in a large Italian region (Tuscany) where a unique single public organisation (Estar) is in charge to provide integrated supply chain services to all the hospitals of the in the Tuscan healthcare system.

Following the suggestion proposed by Terpend et al. (2008) and Ulaga and Eggert (2005), we conducted the analysis for intermediary and end-users.

Estar customers can be divided in two groups: those who have direct contacts with Estar in managing SC related activity (intermediaries), and those who use the product provided by Estar (the end users).

In fact, there may be that customers, with different needs, and engaging in different kinds of relationships with the supplier, evaluate and weight differently the dimensions that determine the overall customer satisfaction. In particular, we tested for the presence of a moderation effect played by the customer typology on the impact of service and relationship quality on the overall customer satisfaction.

Then, a mediation model has been applied, testing the aforementioned hypotheses, investigating which dimension, among service and relationship quality, mostly impacts on the overall customer satisfaction with supplier performance.

The analysis is based on a survey administered via CAWI (Computer Assisted Web Interviewing) to all professionals of the Tuscan health system who directly or indirectly interact with the supplier in their daily work activities (in total 2,154 health professionals). The response rate was 31%.

**Findings**

The moderation model showed how different customers perceive relationship quality as differently influencing (in magnitude) their overall satisfaction. This result was also confirmed by the mediation analysis, that showed how for intermediaries, both relationship quality (OR 7.52) and service quality (OR 1.53) are relevant for the determination of their overall satisfaction with supplier performance, even though relational aspects are more significant, compared to service aspects. Whereas, end users’ overall satisfaction is fully mediated by relationship quality aspects (OR 24.51), and service quality dimension (OR 1.51) is not statistically significant in determining overall satisfaction.

**Relevance/contribution**

This study contributes to the literature because it deals with an under-investigated topic in the inter-organizational research field, that is the determinants of business customer satisfaction (Mustak et al. 2013) in a dyadic public sector context. Indeed, differently from previous public sector studies that focused on network relationships, our paper proposes an empirical analysis on a dyadic supplier-customer relationship in the health care supply chain context.

1. Introduction
Since 90s customer orientation has become one of the main priorities in the public sector. In particular, the customer perspective started to be considered in the designing and provisioning of the service (among others Diefenbach (2009); Dunleavy et al. (2006); Kaboolian (1998); Pollitt (1993); Pollitt & Dan (2011)). In fact, the customer voice (even internal) was deemed fundamental in order to improve the service quality provided by the public entity (Pollitt and Dan (2011). Also in governance networks scholars deeply investigated how to detect and measure the user experience with the service provided by the public organisation remains a key aspect (Klijn, 2008; Klassen, Cepiku and Lah, 2017). Moreover, in the inter-organizational context how to measure and use the customer voice is an issue both in public and private sector where customer voice is considered as a proxy of the value created during the relational exchange between the two parties (Mustak et al. 2016).

Value is a key construct that since 90s has been at the centre of the marketing debate among researchers and practitioners. Scholars have investigated this concept both in business-to-consumers and business-to-business contexts. Irrespectively of the specific context of investigation, scholars agree on the utilitarian nature of value, meaning that the value for customer is the results from an evaluation between benefits and sacrifices. For example, Anderson et al. (1992) defined value in business-to-business contexts as the perceived worth in monetary units of the set of economic, technical, service and social benefits received by a customer firm in exchange for the price paid for a product offering, taking into consideration the available alternative suppliers offerings and prices. More generally, we can say that customers derive value according to the difference between the ‘utility’ provided by attributes of a product and the ‘disutility’ represented not only by the price paid, but also by time, effort and search experienced by the parties (Sánchez-Fernández and Iniesta-Bonillo, 2007).

Very close to the concept of value is the one of perceived value, that is the worth for customers, as a result of an evaluation of what they give compared to what they receive. Hence, perceived
value implies a relational exchange between two parties, where each party gives up something of value in return for something of greater value (Holbrook, 1999).

Several studies investigated the conceptual differences between perceived value and customer satisfaction (among others Boksberger and Melsen (2011); Eggert and Ulaga (2002); McDougall and Levesque (2000)). What scholars agreed upon is that perceived value is a cognitive construct, that may arise both during the pre and the post-purchase phase, both for the actual and the potential customer, who evaluate either the actual supplier offering or the potential one. On the other hand, customer satisfaction is an affective construct, that arises during the post-purchase phase only, and consists in an evaluation of actual supplier’s offerings (Eggert and Ulaga, 2002).

Since 90s, traditional marketing faced the emergence of a new paradigm, i.e. the relationship marketing (Ravald and Grönroos, 1996). The core of relationship marketing is relations, […] and the idea is first to create customer loyalty so that a stable, mutually profitable and long-term relationship is enhanced. In this new reference framework, value is considered to be an important constituent of relationships, […] and one recent research stream in marketing is related to customer perception of value created in on-going relationships. In transaction marketing, this solution is a product in the form of a physical good or a core service. In relationship marketing the solution is the relationship itself and how it functions and leads to value creation and need satisfaction for the customer (Grönroos, 2004).

In the last 20 years, a consistent body of research in the marketing field has investigated the relationships between perceived value, customer satisfaction, relationship quality, and performance. For example, McDougall and Levesque (2000) analysed the factors influencing customer satisfaction, identifying relational quality and perceived value as determinants of satisfaction. Lam et al. (2004) built a model investigating the relationships between customer value, customer satisfaction, switching costs and customer loyalty.
Another stream of research studied how to evaluate the performance of inter-organisational relationships, often stressing the importance of the relational dimension as a key determinant of the overall relationship performance. Giannakis (2007) proposed a framework for the assessment of the performance of supplier relationships, applicable both to the manufacturing and services contexts. This model took into consideration both the supplier and the customer perspectives, measuring their perceptions related to the nature of the relationship, the relational performance of the other party and their own relational performance. Provan and Sydow (2008) provided an overview of how inter-organisational relationships have been evaluated by scholars. They concluded that inter-organisational performance may be measured according to three different levels, i.e. structure, process and outcome. Moreover, they found out how the majority of studies took into consideration either the organizational level or the inter-organisational network as unit of analysis. In the public sector, few attempts have been made to investigate the performance of inter-organisational relationships in the supply chain context (McKone-Sweet et al. (2008); Lai et al. (2002)). One of these is the work proposed by Lega et al. (2013) who developed a framework for the evaluation of the supply-chain performance in the healthcare sector. This was a multi-dimensional framework that considered operational cost, financial benefits and organisational benefits as levels of measurement. The organisational benefits comprehended the evaluation of supplier relationships. Similarly, Ulaga and Eggert (2006) identified benefits and costs building the relationship value dimensions. Among the benefits, they mentioned service support and personal interaction as dimensions characterising the relational aspect, in addition to more traditional dimensions characterising the service quality aspect (product quality and delivery performance).

Therefore, performance evaluation of B-to-B relationships should consider not only service quality aspects, but also customers’ and suppliers’ mutual perceptions related to the quality of the relationship. Indeed, as stated by Cannon and Perreault (1999), *customer evaluations of*
supplier performance and satisfaction with relationship represent important outcomes in business exchange. Benton and Maloni (2005) investigated the relationships between service outcomes, relationship quality, supplier satisfaction and relationship performance, both from the customer and the supplier perspective in the automobile sector. They discovered how the positive effect of service quality outcome on supplier satisfaction was completely mediated by the effect of supplier-buyer quality of relationship. This finding implies that in assessing overall performance of a relationship, what is most important is the relational dimensions, rather than the service outcome.

In this paper, we will investigate the relationship between service quality, relationship quality and overall satisfaction with the supplier performance, as perceived by the customer in a public context. To the best of our knowledge, scholars have mainly focused on performance evaluation of relationships in the private sector. Whereas, studies on the public sector moved away from a dyadic perspective, taking into consideration the performance of the network, especially through a collaborative governance approach (Cepiku (2017); Montoya et al. (2015); Provan and Milward (1995)). As an attempt to start filling this gap, our work will focus on a B-to-B dyadic supplier-customer relationship in the healthcare sector. Moreover, in this paper, we acknowledge that different typologies of customers may experience different perceptions on the relationship performance with the supplier, since different customers have different needs and different expectations. Therefore, we will conduct the analysis considering that the supplier establishes different relationships with different customers. This distinction also answers to the call of Ulaga and Eggert (2005) and Terpend et al. (2008) to consider contextual dimensions (such as the type of industry, the nature and intensity of the relationship, and the category of product or service under consideration), when analysing the B-to-B relationships.

Hence, in this article we first analysed whether or not service and relationship quality have a different impact on the overall customer satisfaction, also by taking into account the typology
of customer. Finally, through a mediation model, we investigated the relationship between service quality, relationship quality and overall satisfaction with the supplier.

2. Research design

2.1 Hypotheses

Relationship and service quality are constructs deeply investigated by scholars as key determinants for the overall customer satisfaction, along with trust, commitment, loyalty long-term orientation and power (among others Giannakis (2007); McDougall and Levesque (2000); Brown et al. (1995); Michie and Sibley (1985)). Therefore, we investigate B-to-B relationships between the healthcare supplier and the health professional customers, focusing on a public context, the Tuscan healthcare sector, rather than on a private one, as analysed in the work by Benton and Maloni (2005). In particular, we focused on the customer perspective, trying to understand what aspect is more relevant when the customer evaluates supplier performance. In other words, we investigated what determinant is mostly impacting on overall customer satisfaction.

Researchers in relationship marketing, deeply investigated the relationship between relationship quality, that is a relational outcome and an overall means of assessing the strength of a relationship between two firms (Caceres and Paparoidamis (2007)), and service quality. In particular, relationship quality may be influenced by service quality, even though service quality can be considered a necessary but not sufficient, condition for relationship quality (Crosby 1990). Given this premise, the first hypothesis we tested is the following:

H1: Service quality has a positive impact on relationship quality.

A great body of literature has focused on the determinants of customer satisfaction, and in particular, some scholars have analysed the relationship between service quality and customer
satisfaction (Caceres and Paparoidamis (2007)). Although this relationship has been investigated in both directions, the majority of findings showed how service quality can be considered as an antecedent of customer satisfaction (Dick and Basu (1994); Anderson et al. (1994); Cronin and Taylor (1992)). In fact, […] *quality is one dimension on which satisfaction is based* (Rust and Oliver, 2000). Therefore, our second hypothesis is the following:

H2: Service quality has a positive impact on overall customer satisfaction.

Wulf et al. (2001) suggested how an improvement in relationship quality generates a higher level of satisfaction, trust, and commitment. Therefore, considering the first two hypotheses and the potential impact of relationship quality on overall customer satisfaction, we propose the following third hypothesis:

H3: Overall customer satisfaction is influenced by service quality and relationship quality, even though relationship quality plays the main role.

Moreover, following the suggestion proposed by Terpend et al. (2008) and Ulaga and Eggert (2005), we separately explored this model for intermediary and end users. In fact, there may be that customers, with different needs, and engaging in different kinds of relationships with the supplier, evaluate and weight differently the dimensions that determine the overall customer satisfaction.

### 2.2 The supply chain in the Tuscan healthcare system

In this paper, the focus of analysis will be the relationship between the public organisation that is in charge of the logistic service provisioning in the healthcare system of the Tuscany region, and health professionals who relate with it. Since 2015, all the logistic activities in the Tuscan healthcare system are carried out by a single organisation, called Estar, that has its own
independence on administrative affairs, legal personality, management and accounting. Estar represents a unique experience in the Italian panorama, since it is not only in charge of the purchasing activities, but it has also to guarantee an integrated supply chain in the Tuscan healthcare system (CERGAS 2017). In addition to the logistic activity, Estar is also responsible for the organisation and fulfilment of the personnel recruitment and payment, public tendering, and information and communication technologies (ICT).

As regards the logistic activity, Estar is in charge of the provisioning of several products, such as medical drugs, medical diagnostic devices, personal protection devices and administrative stuff and it became the unique supplier for all the healthcare authorities for the majority of products. Among the customers we find a plethora of different subjects (nurses, physicians, pharmacists, administrative staff, other health professionals, engineers, etc.), that can be divided in two groups, i.e. one composed by those subjects who have direct contacts with Estar, and those subjects who use the product provided by Estar, even if not interfacing directly with it. These two groups can be defined as the intermediaries and the end users, respectively. More specifically, intermediaries are in charge of the product ordering, whereas the end users are those who only use the products in their daily work activities. In the provisioning of the products, Estar has to guarantee not only service and product quality, but also support in managing the ordering procedure, in case the intermediator needs it. The latter aspect may be defined as the relational dimension, i.e. Estar has to be able to establish a good relationship with its customers, which entails being available when needed by the customer, and provide adequate answers to the customers’ requests.

2.3 Sample and data collection

The questionnaire was developed in collaboration with experts of Tuscany Region Health System as well as Health Authorities (HAs) and Estar professionals. The questionnaire was aimed at collecting and analysing the customers’ experiences (HAs) with the services provided
by the supplier (Estar). In particular, in this article we will focus on a specific service: the logistic. The logistic section consists of 12 questions aimed at understanding the customer satisfaction in relation to both the service and the relationship quality.

The questionnaire was tested with some HAs’ professionals in October 2017, and then administered in November 2017, via CAWI (Computer Assisted Web Interviewing) to all professionals who directly or indirectly (see in the paragraph 3.1 the details) interact with the supplier (Estar) in their daily work activities for a total of 2154 health professionals. The survey was opened for one month and a half to fill in the questionnaire. During this time period, two remainders were sent. Results were collected through the web-based software “LimeSurvey”, and were then analysed in aggregated form using Stata 12.

The overall response rate was about 31%, that is coherent with response rates of other online surveys (Cook and Thompson (2000)). In particular, among the total number of respondents, we took into consideration only those health professionals who, during the last year, utilised, directly or indirectly, the services provided by Estar. Therefore, the respondents’ population we were interested in consisted in 494 health professionals. In particular, 137 out of 494 were the end users group, whereas 357 out of 494 were the intermediaries group.

2.4 Variables

In this article, we will analyse specifically three constructs: customer satisfaction with regards to service quality and relationship quality, and overall customer satisfaction with the supplier performance. The overall customer satisfaction with supplier performance was measured through a 1-5 Likert scale item, that asked the respondents to express the level of coherence between the overall service provided by the supplier and their expectations.
The other two constructs were measured through two different groups of questions, that are reported in Table 1 of the Appendix.

In the statistical model, we also considered the typology of customer, the intensity of needs, measured through the frequency of contacts that in the last year the customer had with the supplier, and the gender of respondents. A complete description of the variables is reported in Table 2 of the Appendix.

We tested for the reliability of the constructs used to measure service quality and relationship quality through the Cronbach’s alpha. For the service quality and the relationship quality dimensions (described in Table 1) the Cronbach’s alpha were 0.79 and 0.82, respectively, showing a more than acceptable internal consistency (Peterson (1994)). Moreover, we conducted an explorative factor analysis to identify the two underlying factors related to the different aspect of the consumer service quality and relationship quality. As we would expect, two factors were extracted from the analysis (eigenvalues >1), i.e. the service quality and the relationship quality factors, which accounted for about 55% and 66% of the total variance of the data.

2.5 Regression analyses

As mentioned in section 2.1, our research hypotheses aimed at investigating the relationship between service quality, relationship quality and overall customer satisfaction with supplier performance. As suggested by Ulaga and Eggert (2008) and Terpend et al. (2008), relationship construct in B-to-B contexts, should be analysed considering also contextual factors that might moderate or mediate the relationship quality evaluation. Following this suggestion, we first
checked for the presence of a differentiated effects of service and relationship quality on overall customer satisfaction, according to the typology of customer. In particular, we tested for the presence of a moderation effect played by the customer typology on the impact of service and relationship quality on the overall customer satisfaction. In fact,

Then, we applied a mediation model, where we investigated which dimension, among service and relationship quality, mostly impacts on the overall customer satisfaction with supplier performance. In other words, we were interested in understanding whether the customer is mostly influenced by the relationship quality, rather than by the service quality, for the determination of her/his overall satisfaction with the supplier.

For the data analyses, we considered the two customer typologies, i.e. the intermediaries and the end-users. In particular, the intermediaries include the following health professional figures: nurses, health assistants\(^1\), pharmacists, and laboratory technicians. All these professional figures are responsible for directly interacting and communicating with the supplier, since they have to make the product orders and have access to the whole tracking process. Whereas, physicians, biologists, physicists, speech therapists, psychologists and veterinarians are the end users, who do not directly engage with Estar, rather they make their requests to the intermediaries, and then use the products, that the intermediary has ordered.

To test the three hypotheses and the mediation effect of relationship quality on overall customer satisfaction, we conducted a regression analysis drawing from Baron and Kenny’s (1986) mediation model. The following three conditions must hold in order to have a mediation effect:

1. The independent variable (service quality) should be significantly related to the mediator (relationship quality).
2. The independent variable (service quality) should be significantly related to the dependent variable (overall customer satisfaction).

\(^1\) Operatori socio-sanitari (oss) in italian.
3. The mediator should be related to the dependent variable when the independent variable is also included in the model. In order to establish a mediation effect, the relationship between the independent variable (service quality) and the dependent variable should be reduced (partial mediation) or should not be no longer statistically significant (full mediation), when controlling for the mediator (relationship quality).

The general mediation model we tested is the following:

\[ H_1: \text{relationship quality}_i = \beta_0 + \beta_{1i}\text{service quality}_i + \beta_{3i}\text{frequency}_i + \beta_{4i}\text{gender}_i + \varepsilon_i \]

\[ H_2: \text{overall satisfaction}_i = \beta_0 + \beta_{1i}\text{service quality}_i + \beta_{3i}\text{frequency}_i + \beta_{4i}\text{gender}_i + \varepsilon_i \]

\[ H_3: \text{overall satisfaction}_i = \beta_0 + \beta_{1i}\text{service quality}_i + \beta_{2i}\text{relationship quality}_i + \beta_{3i}\text{frequency}_i + \beta_{4i}\text{gender}_i + \varepsilon_i \]

A complete description of the variables included in the mediation model is provided in Table 1 of the Appendix. For the regression analyses, the respondents declaring they were not able to provide an assessment to the overall satisfaction with the supplier services were discarded and considered as missing values. That means the 8% of the end users and the 3% of intermediaries did want (or were not able) to evaluate the overall performance of the supplier (satisfaction with Estar).

The second and the third equations have been estimated through an ordered logit regression model, since the dependent variable, i.e. the overall satisfaction with the supplier performance, is an ordinal variable, where 1 represents the lowest level of satisfaction and 5 the highest one.

3. Results

As regards the intensity of needs of the customers (measured through the frequencies of requests made in 2017) showed how the majority of respondents (60%) made a request to the supplier
more than once a month, 19% less than once a month, 21% less than once a semester. Finally, women represented 64% of total respondents.

First of all, we analysed whether or not the customer typology moderated the relationship between service and relationship quality (the independent variables) on the overall customer satisfaction with the customer. By doing so, we created two interaction terms, one composed by the typology of user and the service quality dimension, and the other one composed by the typology of user and the relationship quality dimension. Then, we performed an ordered logistic regression, where the dependent variable was the overall customer satisfaction, the independent variables were service and relationship quality, the typology of user and the two interaction terms, whereas gender and intensity of relationship were included as control variables.

\[ \text{overall satisfaction}_i = \beta_0 + \beta_{si}\text{service quality}_i + \beta_{ri}\text{relationship quality}_i + \beta_{sa}\text{service user}_i + \beta_{ra}\text{relationship user}_i + \beta_{si}\text{frequency}_i + \beta_{si}\text{gender}_i + \varepsilon_i \]

Results in Table 3 reported in the Appendix show how the customer typology moderates the effect of relationship quality on the overall satisfaction. In particular, even if both end-users and intermediaries perceive relationship quality as an important dimension influencing their overall satisfaction (OR for relationship quality is positive and statistically significant), end-users consider relationship quality as two times more important in determining their overall satisfaction with the supplier, as compared to intermediaries. Whereas, this moderation effect does not hold for the service quality dimension, meaning that the influence of service quality on the overall satisfaction is relevant (the OR for service quality is positive and statistically significant) even though almost equal among different customers. Finally, neither the gender nor the intensity of relationship seem to influence overall customer satisfaction.

Subsequently, we tested a mediation model hypothesising that the effect of service quality on overall customer satisfaction is mediated by the relationship quality dimension.
Therefore, we performed a mediation analysis through three sets of regression as reported in section 2.5. The regression models were run separately by the customer typology, i.e. intermediaries and end-users to control for the above mentioned moderation effect.

As regards the intermediaries, we accepted the three hypotheses, hence results reported in Table 4 of the Appendix show that relationship quality positively but only partially affects the impact of service quality on overall customer satisfaction with supplier performance (Model 3). Findings suggest that both relationship and service quality are relevant for the customer in determining the overall satisfaction with the supplier, even though relationship quality has a higher impact on the outcome, compared to service quality. However, even though relationship quality plays the main role in determining the overall satisfaction, intermediaries still perceive service quality as a significant dimension of evaluation. This finding may be explained by the fact that intermediaries are those customers who deeply know the entire provisioning process, including delivery times, typologies of products requested, quantities and quality ordered. Hence, they can properly evaluate the service quality provided by Estar, and they are more sensitive to the supplier performance related to the service offered.

Finally, we estimated the mediation model for the end-users, for whom results show a different dynamic. In fact, relationship quality for end-users seems to completely and positively mediate the relationship between service quality and overall satisfaction, since the OR for service quality is not statistically significant (Table 5 - Model 3 of the Appendix). In other words, in determining end-users’ overall satisfaction with Estar performance, relationship quality, rather than service quality, plays a significant role. This is an interesting result, since it seems to indicate that the end-user, who is not aware about the proper provisioning process functioning, considers only relationship quality aspects as relevant for her/his overall satisfaction with the supplier. For example, in the determination of the overall satisfaction, since end-users do not engage in direct relationships with the supplier, they may be entirely influenced by the reported
dissatisfaction expressed by intermediaries. Therefore, they do not evaluate service quality dimension as relevant in the determination of their overall satisfaction (since they do not know the service process and its details), rather they perceive the relational aspect as the most significant one.

Comparing the odds ratios (ORs) of relationship quality for intermediaries and end-users (Model 3), we can see how the OR for end-users is significantly higher than the one for intermediaries. Whereas, as regards the ORs of service quality, they do not significantly differ among the customer typologies. These findings are coherent with the results coming from the moderation model (Table 3 of the Appendix), that showed how for end-users the relationship quality dimension is more crucial, compared to intermediaries, for determining their overall satisfaction with the supplier. On the other hand, the two groups of customers consider service quality as an equally important determinant of satisfaction.

Finally, as regards the variables controlling for the frequency of relationships and the gender, their ORs are not statistically significant neither for intermediaries nor for end users.

4. Discussion

This paper was aimed at understanding the role played by relationship quality in the analysis of service quality and overall satisfaction. Relationship quality is perceived by users as mostly relevant for determining their overall satisfaction with supplier performance. In particular, following the suggestion by Garbarino and Johnson (1999) about the different role of relationship intensity on overall satisfaction, commitment and trust, we first analysed the
moderation effect played by customer typology on the relationship between service and relationship quality on overall customer satisfaction with the supplier services. Then, given the presence of the moderation effect, we performed a mediation analysis, differentiating among the two typologies of customers, i.e. the intermediaries (who have direct contact with the supplier) and the end-users (who have indirect contact with the supplier). We noticed a positive and significant effect played by service quality on relationship quality; the positive influence played separately by service quality and relationship quality on overall satisfaction and that, when both service and relationship quality are included in the model, the significant and positive impact of service quality on overall satisfaction is partially mediated by the impact of relationship quality for intermediaries and totally mediated for end-users. These findings may be explained by the fact that intermediaries are perfectly aware of the entire process of provisioning and they directly engage with the supplier, hence service quality aspects, such as delivery times, quantitative and qualitative appropriateness of the products with the orders, and so on, are perceived as important features composing their overall satisfaction. However, they seem to attribute more significance to relational quality aspects, such as the ability of the supplier to promptly and effectively respond and satisfy any additional requests of support. To conclude, for intermediaries, relationship quality, rather than service quality, seems to be the dimension that mostly impacts on their overall satisfaction with supplier performance, and this occurs regardless of the product category, the frequency of relationships, or the gender.

Whereas, as regards the end-users, the mediation is complete, meaning that relationship quality dimension totally mediates the effect of service quality on overall customer satisfaction. In other words, end users’ overall satisfaction seems to be influenced by relationship quality characteristics only, rather than a combination of relationship and service quality aspects. This finding may be explained by the fact that end users do not have direct contacts with the supplier, and consequently the worth of mouth took the advantage of the real service quality outcome.
Hence, the overall satisfaction with supplier is not influenced by an evaluation on service quality, rather it is affected by relational aspects only. Coherently with this argumentation, also for end users, this result is not dependent on the product category or the frequency of relationships. Moreover, another interesting finding has emerged from the descriptive statistics. Moreover, about one third of the end users are not able to express an evaluation on the overall performance of the supplier. This reinforces the hypothesis that end users are not completely aware of the provisioning functioning, and hence they are not always able to evaluate the overall supplier performance, those who did are often based on the worth of mouth opinions which are particularly important when the assessment is negative (Soderlund 1998).

From one side we expected that relationship quality had had a higher mediation effect between overall satisfaction and service quality in the case of intermediaries because of the intensity of contacts (see for instance the case of Garbarino and Johnson 1999). From the other side the high role played by relationship quality in the case of end-users who do not have a direct contact with the supplier, the word of mouth seems to have played a very important role totally mediating the perception of the service quality.

5. Conclusions and limitations

This study contributes to the literature because it deals with an under-investigated topic in the inter-organizational analyses that is the determinants of business customer satisfaction (Mustak et al. 2013) in a dyadic public sector context. Indeed, differently from previous public sector studies that focused on network relationships, our paper proposes an empirical analysis on a dyadic supplier-customer relationship in the healthcare logistic context. More specifically, we
investigated which dimension, among service quality and relationship quality, has the main impact on overall customer satisfaction with supplier performance. Given this research objective, the empirical analysis has been conducted on the basis of the results of a survey addressed to all potential customers of the supplier (Estar) that were analysed through a mediation model.

Following the suggestion coming from Ulaga and Eggert (2008) and Terpend et al. (2008), according to which relationships dynamics should consider, among others the nature of the relationship, we checked for a moderation effect driven by the customer typology, and then conducted a mediation analysis separately for the two customer groups identified in this context: intermediaries who have a direct contact with supplier and the end users who have an indirect contact with supplier.

Findings from the moderation model showed how different customers perceive relationship quality as differently influencing (in magnitude) their overall satisfaction. This result was also confirmed by the mediation analysis, that showed how for intermediaries, both relationship quality and service quality are relevant for the determination of their overall satisfaction with supplier performance, even though relational aspects are more significant, compared to service aspects. Whereas, end users’ overall satisfaction is influenced by characteristics concerning relationship quality only, suggesting that service quality dimension is not relevant in determining overall satisfaction. Although both users’ typology are important, empirical evidence suggests that suppliers have to put in place different strategies to enhance users perception about the overall performance.

Future research should investigate these relationships also considering other aspects analysed in the literature such as trust, power, cooperation and long term orientation (Abdallah et al. (2017); Chumpitaz Caceres and Paparoidamis (2007); Lam et al. (2004); Ganesan (1994);
Skinner at el. (1992)). Even though there is the need to confirm this evidence also in other context and sector to generalize the results, to the best of our knowledge, this study represents the first explorative attempt to analyse B-to-B relationships in the logistic service of the healthcare system.

Appendix

Table 1 – Service and quality items

<table>
<thead>
<tr>
<th>Service quality items</th>
</tr>

<tr>
<td>- 0-5%</td>
</tr>
<tr>
<td>- 5-10%</td>
</tr>
<tr>
<td>- 10-25%</td>
</tr>
</tbody>
</table>

On a scale from 0% to 100% express the following evaluations:
• 25-50%
• 50-80%
• 80-100%

1 % of times when the accompanying documents were not coherent with the order
2 % of times when at least one ordered product was missing
3 % of time when it was necessary to repeat the order
4 % of times when it was necessary to order missing products with urgency
5 % of products not coherent with the order
6 % of products missing

Relationship quality items

Likert Scale 1-5 adopted:
• 1=completely disagree
• 5=completely agree

The following dimensions are respondent to the expectations:

1 Information on the availability of products in the warehouse
2 Tracking of the orders
3 Knowing who (among the supplier company) to call in case of need
4 Support provided by the supplier in solving problems related to the order management

The role of brokering in healthcare networks: what does it mean for reforms, practitioners and patients?

Abstract

Well-integrated systems are required to deliver effective healthcare services. Research suggests misaligned organisational and functional boundaries still thwart effective patient care. Using social network theory and knowledge transfer framework we examine two long-term condition health networks where brokering occurs to bridge the gaps in provision or information exchange. The experiences of patients, relatives and healthcare practitioners illustrate where information/knowledge is transferred, translated and transformed across organisational and functional boundaries. We propose brokering is essential to the integrated healthcare system. Areas of further research include power of brokers and the value and cost of brokering.

Keywords: Health, Broker, Networks

Introduction

Early studies on service management consider the interaction between service users and service providers in the process of creating services (Fuchs, 1968). Service operations management continues the focus on service design, particularly the interaction between the professional and the customer/service user. Anecdotally we know that patients and relatives bridge gaps in health care processes, systems and services to ensure relevant information gets to the necessary healthcare professional(s). What is not well understood is the nature of this brokering role, the types of gaps that are brokered, and the brokering strategies used. Much of the previous research has focused on the
relationships between service users and providers. For example, Harvey’s (1990) research in social services explains how relationships in professional services influence process (re)design and consequently service outcomes. The level of trust and the balance of power in professional service organizations can also influence the relationships among professionals, service users and managers. In subsequent research, Harvey (1992) recognized that the knowledge gap between the professional and the customer requires attention if services are to be improved.

It is well-recognised that agents (often-termed actors) within a network can help to bridge the knowing-doing gap by acting as conduits for the transfer of resources including advice, social support and information (Moolenaar and Sleegers, 2015). Social network theory (SNT) (Reagans and Zuckerman, 2008) helps to examine connections and information flows between the actors and across two healthcare networks to establish the ‘structural holes’ that may exist (Li and Choi, 2009) and identify where actors act as brokers to bridge the gap between unconnected agents or organisations in the network.

For a broker the challenge can be to transfer information to an agent who will accept and value it (Burt, 2005). Brokers can connect groups by engaging in “transferring, translating, and transforming” practices (Carlile, 2004) and developing work practices, repositories, specifications, and standards that support communication across boundaries (Fernandez-Mateo 2007). This process facilitates negotiation that allows localized knowledge to be transformed into jointly produced knowledge that transcends each group’s local interests (Kellogg, 2014).

We propose brokering is an essential role in the design and delivery of integrated healthcare networks/services. Using social network theory and Carlile’s framework this study aims to understand the nature of brokering roles occupied in two chronic long-term health networks. This study addresses the following research questions:

RQ1. What is the nature of the structural holes (gaps) that exist within two chronic long-term condition care networks?

RQ2. What type of brokering roles do healthcare professionals, patients and relatives play in bridging the gaps in the two care networks?

RQ3. What strategies do brokers use to ensure information flows support the effective delivery of care?

A brief review of the social network theory, specifically structural holes, follows this introduction. The next section introduces Carlile’s framework and its use in understanding the transfer of knowledge and information. The methodology employed for this study is then discussed along with the results of the study. The paper concludes with a summary of the findings in relation to the research questions posed above, limitations of the study and areas of further research.

Social network theory
Social network theory has a long and distinguished history in the social sciences and psychology where it has been used to investigate human social organisation (see Scott 2000) with its main strengths being the potential to address population-level or cross-population-level problems by building up complex social structures from individual level interactions. However, the appeal of the networks approach goes well beyond sociology and psychology and has widespread technological applications as well. Anything from transport networks (Sen et al. 2003) to communication systems such as
the internet (Tadic 2001) can be considered as a system of interacting components. In biology, the network approach has been used in various areas, as biologists have realised that to better understand complex systems, we need to study interactions between components of the system not in isolation but as part of a network of interactions Kim et al., 2011). This notion of understanding the interactions and connections in the system can be applied to healthcare networks.

Social network theory encapsulates the need to develop an understanding of structural holes (Burt, 1992) and bridging (Obstfeld, 2005) as agents can broker the movement of information and resources (Peng et al, 2010). Agents can operate as conduits for the transfer of resources including advice, social support and information (Moolenaar and Sleegers, 2015). A central position supports the agent in operating as a broker through bridging the structural hole between unconnected agents in the network. Bridging the hole allows the broker to create value where the value of the information presented resides in someone else accepting it not with its provider. The challenge for the broker is to transfer the information to an agent who will accept and value it (Burt, 2005).

For manufacturing, this necessitates the operation of an information decoupling point to bridge and deliver value across two operational approaches (e.g. from forecast-driven to demand-driven approach). Within healthcare the decoupling point occurs at several points, for example the point where patient demand meets A&E plans, or discharge from acute (hospital) care to the community. Clearly, the independent providers are aware of each other’s existence but the information flows are not linked.

**Brokering structural holes within and across organisations**

Previously, brokering in organisations has been linked with Burt’s (1992) structural holes theory. He argued that all organisations contain structural holes which can be defined as “non-redundant” relationships between two or more actors. In simple terms, if a hole is redundant this suggests the connections to bridge across are not needed for the effective functioning of an organisation or the necessary information can be provided through other equally effective and efficient routes. However, if they are “non-redundant”, new connections are required. Such connections are crucial to ensuring an organisation operates effectively and achieves its objectives. In short, structural holes are places where people are disconnected in an organisation and /or information flows required to make the organisation work effectively are disrupted (Monge and Contractor, 2003). While structural holes disrupt the flow of valuable information in an organisation they provide opportunities to those who can re-make (broker) those connections. In simple terms, by spanning structural holes brokers can perform an “intrapreneurial” role within an organisation, by leveraging social capital from the new non-redundant connections between organisational actors (Kuratko et al., 1990; Heng and Loosemore, 2013). In this case, social capital is the value that can be derived from an actor’s relationships in an organisation (Brass, 2003). For example, if a broker sits between two other actors and controls the flow of information between them, then they are in a powerful position.

Baker and Obstfeld (1999) argue that brokers tend to employ two distinct types of strategies in reconnecting organisations: “disunion” and “union” strategies. In the disunion strategy, the broker pursues the active separation of disconnected actors therefore becoming a bridge between two disconnected actors but not allowing them to interact directly. Conversely, in the union strategy, a broker closes the network holes between two disconnected actors enabling them to communicate directly or through a common third party. In reality, a combination of both approaches tends to be adopted. The above ideas have been informed by the social network theory which focuses on the
relationships between actors rather than the attributes of actors in an organisation (Wasserman and Faust, 1994). Social network theory argues that an actor’s influence in an organisation is not only a function of their legitimate power but a function of their position in that network. “Central” actors located at the intersection of information flows between other parties command the most powerful positions while those on the periphery of a network command the least powerful positions. These ideas can inform us of the role of healthcare staff and patients/relatives might play in healthcare services. This brokering role may be more prominent due to the current movement towards integrated health and social care services, which seems to be a desire within and outside of the UK health system (e.g. The King’s Fund, 2018). Much of the literature, until now, has focused on roles (often managers e.g. Currie et al., 2015) within the organisation – hence reference to it being an “intrapreneural” role (Heng and Loosemore, 2013). Here we investigate the roles of healthcare professionals within the two healthcare networks as brokers, which can include primary and secondary care organisations. We also consider the brokering roles assumed by patients and their relatives, which could be described as an “entrepreneurial” role.

Transfer of knowledge and information
We are interested to see how the structural holes are bridged in relation to managing information flows. Specifically we draw on Carlile’s framework which is used to help understand how the exchange of knowledge at a boundary is managed. In the literature distinctions are made between three types of boundaries and how these are connected to knowledge. The first is difference in knowledge which refers to a difference in the amount of knowledge accumulated (e.g. novice and expert). This in turn creates differences in levels of experience, terminologies, tools and incentives. As the difference in the amount of domain-specific knowledge increases between actors/agents, the amount of effort required to adequately share and assess each other’s knowledge also increases.

The second knowledge difference at the boundary is dependence – without dependence, difference is of no consequence (Carlile, 2004). Knowledge can be different in kind and degree, which means managing dependencies requires the capacity to develop an adequate understanding and common knowledge as resources and tasks change. The third difference relates to how novel the circumstances are. This novelty could relate to actors being asked to share knowledge with others and to access from others. Common knowledge is a boundary object (Carlile, 2002) which actors use to communicate across domains. When novelty is present both the capacity and the ability of the actors to represent the knowledge become important issues (Carlile, 2004).

Carlile’s (2004) integrated/3-T framework (see figure 1) for managing knowledge across boundaries draws on Shannon and Weaver’s (1949) three levels of communication complexity – syntactic, semantic and pragmatic. The most common phrase used to describe movement of knowledge in organisations is “knowledge transfer” (Argote, 1999). This information processing (also referred to as syntactic) approach is the most dominant view in organisation design and forms the basis of most technology-based approaches to knowledge management, where the main focus is on storage and retrieval of knowledge (Davenport and Prusak, 1998). This assumes there is sufficient common knowledge; simply transferring knowledge can be problematic when novelty arises as it may be difficult to represent the differences and dependencies that are likely to be present.

A semantic boundary occurs when novelty makes some differences and dependencies unclear or some meanings ambiguous. This might require translating knowledge where
mechanisms or roles are developed to help create ‘shared meanings’ – these might include cross-functional teams, co-location and individuals to operate as brokers and translators (Hargadon and Sutton, 1997). The ability to externalise knowledge – making tacit knowledge explicit is critical to the flow of information. The ability to negotiate varying interests/agendas of the different actors is also important.

The pragmatic boundary refers to situations where novelty results in different interests among actors that need to be resolved. This means that domain-specific knowledge and common knowledge will need to be transformed to effectively share and assess knowledge at the boundary. Team working is one mechanism to help transform knowledge along with boundary objects such as drawings and other visuals (Carlile, 2002).

Figure 1. An integrated 3-T Framework for Managing Knowledge across boundaries
Source: Adapted from Carlile 2004:258)

The framework is helpful to categorise and show the relative complexity of a boundary and to identify the different types of processes that exist. The arrows moving from known to increasing novelty indicates new differences and dependencies exist and these need to be identified and understood. Although the line between each type of boundary is clearly demarcated, the transition where one ends and another begins is not often easily identified by the actors/agents involved. The figure also depicts the hierarchy of increasing complexity, where a more complex boundary requires the capabilities below it. This framework can be used to describe the mismatches that can occur between the type of boundary and the capacity/process used to share knowledge. In this study, we employ the framework to help to understand the gaps and boundaries between patients, relatives and staff within two patient networks.

Methodology
This qualitative study was conducted within two healthcare networks for the delivery of services for two long-term conditions in the UK, respiratory and Huntington’s disease (HD). Experienced-based interviews were conducted with 45 healthcare practitioners, patients and relatives (see table 1) from the two pathways, which included secondary (hospital) and primary (GPs) care. NHS ethical approval was obtained and consent
sought from participants. The inclusion and exclusion criteria for selection of participants are shown in table 2.

The semi-structured interviews were conducted either at the participants place of work or, in the case of patients and relatives, at their home. The duration of the interviews was typically between 45 to 90 minutes. The interviews were transcribed verbatim, and manually coded and analysed using King’s (2004) thematic framework. This paper reports on the themes that related to the type of boundaries, the processes used to transfer of information and brokering roles operating within and across the two networks. Other themes directly associated with the design of the patient pathway/network are outside the scope of this paper and have been previously reported (Williams, 2017).

Results and Discussion

From the analysis of the interview data, it was evident healthcare practitioners, patients and relatives occupy brokering roles in both pathways. Using SNT and Carlile’s (2004) framework, this paper identifies the gaps and structural holes in the network and reports on the activities used by the participants to transfer, translate and transform information across these interfaces. Much of this activity occurred at the interface of professional, functional and organizational boundaries. Patients (and relatives) were asked to describe their journeys prior to and since their diagnosis. Healthcare professionals from both the community and hospital providers were asked to share their understanding of the care network and how it works. Mapping the experiences of participants enabled us to identify the structural holes in the network and classify the activity in terms of the type of brokering undertaken. The results show patients and relatives assume or expect the healthcare network to be connected but in ‘reality’, they have to pick up a brokering role. For both respiratory and HD patients and relatives this largely required transferring information between healthcare professionals and their organisations. In some instances, particularly for HD patients and relatives due to the rarity of the disease, translation of the information and knowledge of the condition was also required on admission to acute services.

Specialist healthcare practitioners often occupied a brokering role within both networks. These can be located in the hospital (respiratory) or in the community (respiratory and HD) and regularly ‘inreach’ or ‘outreach’ to services in order to bridge
the gap between acute and community care and/or health and social care. For example, one respiratory staff participant explained, “If the patient is not known to us on the ward we contact the community respiratory team.” Although there is rhetoric to move to integrated care in reality this model of care is not fully implemented in the UK health and social care system and is largely dependent on the informal brokering roles bestowed on practitioners, patients and relatives.

Table 3 provides examples of the main boundary issues experienced by the participants from both networks. The types of boundary are classified according to the 3-T framework. Staff, patient and relative participants were found to engage in all three connecting practices – transferring, translating and transforming information. Similarly, all three types of boundaries were found to exist in one or both of the networks. The extent these practices were effective was influenced by language (ability to translate), ‘power’ relationships (ability to be heard/respected) and being able to bridge the gap (knowledge of network). Participants shared many examples of syntactic boundaries where they needed to transfer information. Often this was due to poorly integrated information systems across different organisations within the network. The HD network required information to be transformed by the family when interacting with services that had limited or no knowledge of the condition (e.g. hospital or GP practice). The participants from the HD specialist community team provided examples of transforming information to enable their patients and relatives to interact and access public services such as housing, benefits and transport.

However, information may not be integrated across the various organisations/services. Chronic Obstructive Pulmonary Disease is the second highest reason for unplanned</td>
<td>Rare illness estimated to be 6000-8000 cases in UK. Knowledge held by patient, relative or community specialist team (not present in all areas of UK). Less likely to be known in hospitals.</td>
<td>Syntactic (R) Semantic (HD)</td>
<td>Transferring information (R) Translating information (HD)</td>
</tr>
</tbody>
</table>
Many of the issues raised by staff and patient/relative participants refer to gaps and structural holes that exist within the networks. Often these gaps are due to poorly integrated IT systems where information is not transferred across the organisational boundaries e.g. primary and secondary care. Other gaps exist due to the lack of or incomplete common lexicons to translate the information e.g. discharge letter. As Carlile (2004) argues as the novelty increases in relation to the information the greater need for information to be transformed. The HD network provides examples of where healthcare professionals frequently act on behalf of their patients and families to broker the knowledge boundary between health and other services. The rarity of the HD increases the novelty of the information and highlights the need for participatory and relational nature of the actor’s role. Previous research has shown that actors can misrecognise novelty as something that is already known (Martins and Kambil, 1999) or discarding what is novel as irrelevant (Perrow, 1994).

In this study, the need for brokering occurred at various points within both networks:

- Patient/relative between healthcare professionals
- Specialist healthcare professional between other healthcare professionals
- Specialist healthcare professional between patients/relatives and other public services.

Where specialist healthcare professionals are brokering across healthcare professionals in their own organisation (e.g. respiratory specialist nurse brokering between the respiratory ward and A&E) this can be described as intrapreneurial role. The role of patients and relatives bridging across organisations can be described as an entrepreneurial.

The structural holes identified from the interviews were largely due to poorly integrated systems and/or misaligned organisational boundaries. None of the participants described or recognised their experiences as bridging gaps in the provision or receipt of care. The brokering activities were largely about connecting (union) actors within the system to aid the flow of information, knowledge and value, which then aids patient flow. No examples were identified in this study where participants undertaking
a brokering role purposely aimed to reinforce the gap and disunion the actors within the network (Baker and Obstfeld, 1999). However, what is not clear from this research is the action taken by the organisations to ensure either the brokering role is formally recognised or steps are taken to bridge the structural hole occupied by the broker. Overlooking the brokering activity can potentially introduce vulnerability into the network. Using a range of brokering strategies and understanding the brokerage behaviour and the impact of information/knowledge brokerage on patient outcomes is an important area for healthcare organisations and networks to consider (Heng and Loosemore, 2013).

**Conclusion**

Uniquely this paper focuses on providing the experiences of healthcare practitioners, patients and relatives occupying a brokering role within designated long-term condition healthcare networks. Using SNT and a brokering framework, this research provides insight to the types of brokering that occur. This research considers three questions, the first being the nature of the structural holes (gaps) that exist within two networks. Using Carlile’s framework the three boundaries types were identified – semantic, syntactic and pragmatic, with union bridging activity being undertaken by staff and patient/relative participants (Baker and Obstfeld, 1999). Our second area of enquiry was the type of brokering roles occupied by healthcare professionals, patients and relatives. The examples provided by the participants suggested most of the bridging (union) activity was connecting poorly-aligned organisations and functions. Building on the bridging activity, knowledge transfer, translation and transformation were all evident from the analysis of the interview data. The final question considered the strategies employed by brokers to ensure information/knowledge flows to support the effective delivery of care. All three examples of knowledge transfer were identified – transfer, translation and transformation.

We propose brokering is essential to the integrated healthcare system sought by the NHS as the future model for the health and care system in England (The King’s Fund, 2018) and therefore call for formal recognition and training for those occupying this space to ensure equity across all those delivering and receiving healthcare. Although this research has a UK focus, the move towards integrated health and social care systems is a universal goal. Important areas of research not covered here is the power held by the broker, the value of brokering and the cost of brokering.

Abstract

Care for older people must often be provided across health and community settings. The fragmentation of care processes and lack of continuity are common problems. Better and more efficient care models need to be developed to meet the needs of the growing population of older people. Based on case studies in the Swedish health care system this paper focuses on identifying strategies for achieving integrated care for older people. Five key strategies are described: integration of care processes, development of targeted care services, establishing home-based care services, coordination of care services, and use of technology to streamline care.

Keywords: Integrated Care, Care for Older People, Logistics and Quality Management in Health Care

Introduction

More people live longer and with age comes diseases. Improving care for older people belongs to the most important development priorities in the Swedish health care system. Many chronic conditions are also strongly related to aging and a high proportion of older persons suffers from simultaneous presence of diseases, and cognitive and physical functional limitations (Marengoni et al., 2011). Care for older people must often be given across primary care centres, specialist units, diagnostic centres, emergency departments, home care agencies and nursing facilities. Care processes then becomes highly complex with diagnostics and treatments requiring input from multiple health care providers (Meijboom et al., 2011). Within each care unit, a patient meets a number of physicians, nurses, medical assistants and other caregivers (Ahgren and Axelsson, 2007). Poor transitions between health care providers, lack of continuity and long waiting times are frequently mentioned problems (Stiernstedt, 2016). Problems as lack of continuity and long waiting times often occur due to communication and coordination deficiencies in the health care system where care units often operate as “silos” without the required integration between them (Coleman, 2003). It indicates that the current health care system is not designed to meet the needs of older people. Consequently, new care models need
to be developed to improve continuity and quality of care for this special group of patients (Berglund et al., 2015).

Integrated care models for older people represent a distinct research stream due to the high specificity of care needs and the requirement to integrate primary, secondary and community care (Berglund et al., 2015). The aspects of care desired by older people include needs for convenient access to caregivers, support from a single coordinator, clear communication of care plans, and informational, management and relational continuity of care. Older people also wish that caregivers acknowledge the fluctuating and unique nature of their needs and have a caring attitude (Bayliss et al., 2008, McCormack et al., 2008). There is a growing evidence that integrated care models have a positive impact on patient outcomes, quality of care and cost savings (WHO, 2016). It is therefore important to have a conceptual understanding of different strategies to integrated care, as well as practical examples of how such strategies can be realised. Hence, the purpose of this paper is to contribute to the body of knowledge on key strategies for achieving integrated care for older people.

Frame of references

Integrated care
The current health care system is designed to primarily treat urgent and episodic health problems but does not necessarily serve the needs of a growing population of chronic, multimorbid and older patients (Lillrank, 2018). Care of these patients is characterised by a higher need to collect and respond to more symptom, diagnostic and monitoring information and often implies multiple transitions between health and social care providers (WHO, 2016). Lack of integration often leads to a degraded experience for patients and to a qualitatively poorer health and social care. Further, common shortcomings are increased costs, partly because treatments or examinations need to be repeated unnecessarily or since it drives more resources to coordinate unstructured care processes (Clarke et al., 2016). Additional, the responsibility for care coordination often falls on patients and their relatives who are not always capable to navigate and manage their care process (Bodenheimer, 2008).

Integration and coordination of care across settings and providers are considered as two central approaches to managing and improving patient flows (Singer et al., 2011, Goodwin, 2016, Bodenheimer, 2008). Integrated care is often described as contraposed to fragmented and episodic care (Kodner and Spreeuwenberg, 2002). The goal of integrated care is to enhance quality of care and quality of life for patients and to improve system efficiency by reducing the number of hospital stays, shortening the length of stay in hospital, avoiding unnecessary readmissions, and reducing the need for social care services (Damery et al., 2016, WHO, 2016). However, there is no established definition of integrated care and synonymous concepts such as coordinated care or seamless care are used (WHO, 2016). It is likewise suggested that the conceptual elasticity of integrated care is a result of the polymorphous nature of the practice (RAND, 2012). The definitions of integrated care often reflect perspectives of different stakeholders as for example health care professionals or patients (Goodwin, 2016). In this paper we take the perspective of health and social care providers and adopt the following definition: “Integration is a coherent set of methods and models on the funding, administrative, organisational, service delivery and clinical levels designed to create connectivity, alignment and collaboration within and between the care and care sectors” (Kodner and Spreeuwenberg, 2002).
Strategies to integrated care for older people

A strategy can be defined as the pattern or plan that integrates major goals, policies, and action sequences into a cohesive whole (Lampel et al., 2014). This paper deals with strategies to integrated care for older people who often have multiple chronic conditions and receive care from many different health and social care providers. The strategies focus therefore on organising care around the individual patient’s needs and effectively managing collaborations across organisational boundaries (WHO, 2016, Reed et al., 2005). Examples of strategies identified in the literature include changing organisational structures and processes to support integration of strategic, managerial and service delivery levels, working in multidisciplinary and multiprofessional teams, communication and information sharing across care sector systems and health and social care professionals, and case management for identifying patient needs and developing care management plans (Johri et al., 2003, MacAdam, 2008, Reed et al., 2005, Dubuc et al., 2013).

Design/methodology/ approach

To identify strategies to integrated care for older people case studies at different levels within the Swedish health care system were conducted. The study design is based on qualitative research with an inductive approach (Patton, 2002). Hence, the key strategies presented in this paper are empirically driven.

Study context

In Sweden, the responsibility for care to older people is divided between regions and municipalities, which are governed by politicians elected by the citizens. The health and community care are publicly funded. Regions and municipalities can contract private providers, but purely privately funded health care is, however, marginal. Compared to other countries, the whole Swedish health care system is highly decentralised. The 21 regions are responsible for providing primary and secondary care services. The 290 municipalities are responsible for the community care and health care providers in the regions need therefore to collaborate with several different municipalities. Table 1 provides an overview of how the responsibility for elderly care is divided between regions and municipalities.

However, the main responsibility for health policy on a national level lies on the Swedish government and parliament. One of the major challenges in care provision for older people in Sweden is collaboration and coordination of care across health and social care providers (NBHW, 2017). The development towards more integrated care was actualised with the introduction of new law on collaboration when discharging patients from hospitals in 2018. Different strategies are currently implemented at different care levels.
within the Swedish health care system to meet the legal requirements and development needs. Since strategies can take different forms and result in diverse outcomes (Lampel et al., 2014) this paper includes both intended, unrealised, deliberated, emergent, and realised strategies.

**Data collection**
The results are based on case studies carried out at national, regional, and local levels of the health care system. At national and regional levels, the focus was on identifying policies, guidelines and development plans for quality improvement of elderly care. At local level, three development initiatives were studied in two different regions, which together cover 20% of the Swedish population. The three development initiatives are named as “HälsoStaden”, “Future care unit” and “Proactive primary care”. “HälsoStaden” (“Health city”) is a project co-financed by EU where community, primary and hospital care are integrated and managed through one organisation. “Future care unit” is a pilot project aiming to develop and test a new care unit focusing in the needs of older people. Lastly, “Proactive primary care” predicts older patients with risk of hospitalisation and offers them proactive care services.

The data were collected during year 2017 to 2019 through interviews (n=33), meeting observations (n=10) and document studies (n=59). An overview of data collection is presented in Table 2. The interviews were semi structured and were conducted until reaching the data saturation point. The interviewees were chosen to represent different professions and positions. Each interview took about 1 to 2 hours and was taped and transcribed. Participant observations were carried out of meetings related to planning and evaluating development activities. The meetings were documented by free structured notes. The document reviews included national and regional strategy documents, activity reports, handling plans, documented procedures and meeting minutes.

A case study protocol was also established to secure the reliability of the data (Yin, 2013). It describes the entire set of procedures involved in the data collection and included: list of all documents studied, interview guides, transcribed interviews, and meeting notes.
The collected data was analyzed using qualitative content analysis (Patton, 2002). The analysis implied identifying key concepts as initial coding categories related to strategies to integrated care. Two researchers independently coded the data and then jointly discussed the results to establish code content consensus.

**Findings**

Based on the analysis of the empirical data five key strategies were identified: *integration of care processes, development of targeted care services, establishing home-based care services, coordination of care services, and use of technology to streamline care.* The five strategies are described below.

**Integration of care processes**

The first strategy is *integration of care processes* where two types of integration were identified to align the three levels of care: community, primary and secondary care. The first type, *organisational integration*, implies that health and care services are managed within a single organisational structure. For example, the case: “Hälsostaden” integrated primary, community and selected hospital care providers into one organisation with a joint management team. The organisational integration created a common ground for collaboration and development but was not sufficient to achieve greater integration benefits. The legal and regulatory requirements for a code of conduct and professional boundaries required further integration and coordination mechanisms.

The second type of integration focused on managing transitions between care levels to establish coordinated and coherent care processes. This integration type, which can be referred as a *vertical integration* of health and care providers, was observed in all three local development initiatives. Collaboration teams were created to develop working procedures and define responsibilities of providers involved in the care process. A common trigger for development work were discussions around specific patient cases with nonconformities and quality issues. This joint discussion contributed to better understanding of realities that govern different providers and identifying root causes of problems. Hence, from contract to operational everyday problems concerning the patient. The solutions involved defining the course of activities, developing best practices and standardising communication and information exchange, which is illustrated by the following quote:

“It can be e.g. about how, in what way we agree to contact each other, contact channels are such a thing. Should we make a phone call, fax or maybe email? It can be such a simple thing. Can we decide on one day of the week when we do individual care plans for our patients? It is more easy then when I meet the patient to know when there is a time next week. I can announce this time to relatives and patients. So, it is very much about who does what and in what order and that we all agreed on this. It is also about telling each other how our organisations work”.

**Development of targeted care services**

The second strategy contains initiatives that imply the *development of targeted care services* for older people. Since, the current health care system is not designed to fulfil the needs of older people, better and more effective ways of providing care need to be developed to address the problems. One example from the case studies is a *day care unit* opened in a hospital to fill the gap between primary care services and in-patient hospital care. There is a wide range of care services, for example regular blood transfusions, draining away excess fluid, monitoring some chronic diseases that are not provided by primary care, but actually do not require hospitalisation. The day care unit addressed these special needs of older people so emergency visits and hospitalisations can be avoided. The physician working at the unit was part-time employed at the emergency department,
which helped to identify patients who could be cared for in an alternative setting. The day care unit is in a development stage and the range of services extends based on arising needs.

Another example is a proactive primary care service targeting patients over 75 that are likely to be hospitalised. Patients identified with digital prediction model are approached by a multidisciplinary care team that evaluates patient’s social and medical condition and creates an individual care plan. This proactive approach aims also to reduce hospitalisations and emergency visits as patients are cared for before an urgent care need arises.

One more example is medication reviews provided by caregivers to assess multiple medications and identify risks of side effects, medicine interactions and other medicine problems. It is a work method of reviewing all drugs prescribed and used by a patient to ensure a correct and up-to-date drug list.

Establishing home-based care services

The third strategy is establishing home-based care services which contains initiatives that aim to reduce the number and length of hospitalisations for older people. One example is mobile teams making home visits for both planned and acute medical care. The team may consist of caregivers from primary/secondary and community settings, frequently a physician and a nurse equipped to perform care services at home. The type of care provided varies but, in many cases, there are care services that would require an inpatient hospital stay. The patient needs to fulfil some criteria and make an active choice to be registered as a mobile team patient. One example of admission criteria is that the patient is over 75 years old, has more than three chronic diagnoses, have been admitted to hospital three or more times during the last 12 months, has six or more permanent medications, and has already some home-based health care services. One important service provided by mobile teams is assessing the holistic care needs of the older person and establishing an individual care plan. Mobile teams enable older people to live at home or in other accommodation form with a home-like environment as long as possible and to receive care outside the hospital setting. The anticipated effects are a better quality of life for patients and the reduced number of unplanned hospital admissions and emergency visits.

The other example is integrated discharge from hospital care. The main goal is to ensure a safe and effective transition from inpatient care to a home environment. Integrated discharge means providing support to older patients so they can feel comfortable to take over responsibility for their care and life and thus reduce the risk of developing a dependence on care services. Hence, the service aims to develop or regain the individual's previous functional ability and independence as quickly as possible. It is also important from a hospital perspective as new patients cannot be admitted when treated patients occupy beds. Integrated discharge is a time-limited service, which ends when no longer needed or when regular home-based health care takes over. Some municipalities work with dedicated discharge teams while others provide the support within regular home-based health care services. For those patients not connected to the home-based health care services an alternative discharge support is offered through a contact nurse who makes home visits two days after discharge.

Coordination of care services

The fourth identified strategy to integrated care for older people is coordination of care services using dedicated roles and/or other coordination mechanisms as standardisation of work and multidisciplinary work. Coordination is needed both between caregivers and with the patient.
Coordination through standardisation means setting rules and procedures specifying what and how different tasks should be done. One of the most frequent examples identified in the empirical material is the coordinated individual plan (CIP), which gained attention with the newly established law in Sweden on collaboration on discharge from hospitals. CIP is a plan jointly developed by all involved providers and with the participation of the patient and relatives. The plan should define care services needed by the patient and clarify who does what and when. CIP ensures an effective collaboration and coordination of care services and gives the patient and relatives an understanding of who is in charge of the care, so they don’t have to spend time and energy on finding and coordinating the needed services themselves.

A common strategy is also to assign coordinators with the overall goal to ensure informational, management and relational continuity of care. One example is a collaboration coordinator that is not linked to a specific patient but has the primary task to manage handovers and ensure that information is transferred between caregivers. This type of coordinator contributes to informational and management continuity of care. Another example is a coordinator assigned to a specific patient with the task to communicate with the patient, shape the care process according to the patients’ needs and support the patient and relatives during hospital care and transition to home. Coordinators with this role are important to ensure the relational continuity of care.

The third example is “elderly pilot” whose role is helping patients and their relatives to navigate and access different care services. It can be about available options depending on where the older person lives and what kind of service is needed. It can also be about practical issues such as safety alarms, food deliveries or personal care.

The last example are coordinators in the community care who support patients after the hospital discharge. This support may for example imply daily telephone contacts to convey a sense of security for patients and check if the recovery progresses as expected. This service is provided to patients who do not have a dedicated home-taking-team, but have granted home-based health care services.

Use of technology to streamline care
The last strategy identified is about using technology to streamline care. Several strategies at both a strategic and an operative level as well as intended and emergent strategies are described in the empirical material. Integration of IT systems, use of medical technology, e-solutions to enhance delivery of integrated care are examples of this strategy.

One important barrier to integrated care is the transfer of medical and care information across organisational settings. The providers of primary, secondary and community care use different IT systems and register patient records locally. This is due to the requirement of high level of security, secrecy and traceability when information is shared between different organisations, so the patient integrity is not violated. Different solutions are implemented at different levels of the health care system to address the problem. At national level a digital platform called “The National Patient Summary” is implemented to provide authorised health and social care providers with access, with the patient's consent, to medical records documented in other regions, municipalities or private care providers. The platform automatically retrieves information from different IT-systems and an authorised health care provider can share and access their own and other care providers medical records. Another example is “My Plans” which is an IT-support for collaboration and joint planning of patient care processes, for example during the discharge.
Furthermore, a big IT project is in the starting blocks in one of the regions studied. The project aims to develop a joint patient record system, which enables process-oriented communication between caregivers and with the patient itself. It should be a comprehensive system shared between all public and private health and social care providers with a single login for employees and only one journal per patient. Relevant information about a patient should be accessible at one place for all caregivers involved in the patient care.

Several technical aids for supporting older people in their home were also identified in the empirical material, such as Thumb ECG (to send information on cardiac status instead of doing cardiac examinations in hospitals), digital home alarms instead of analogous, digital diapers (to send information in order to pinpoint help to toilet service), and drug dispenser and drug robot to automate drug handing.

IT is also used for control and management of care services, for example, by digital speedometer to see the actual number of inpatient days before home taking by the municipality since the region's statistics are delayed by two months. Other examples are measurement and follow-up of mobile team's activities and results, and a system to notify potential readmissions.

**Discussion and conclusions**

This paper outlines strategies to integrated care and provides examples of how these strategies can be realised. The strategies identified in the empirical material are compiled into a model presented in figure 1.

![Figure 1: Integrated care model for older people](image)

The model above implies several important implications for the care delivery of older people. First, in order to address the fragmentation and lack of continuity, care for older people needs to be organised in a process-oriented way. The growing specialisation of care has led to strong functional organisation and “silo mentality” with no clear responsibility for patient flows. Care for older people is provided in a complex system with multiple providers that can have different, sometimes conflicting, objectives. The
process orientation in the Swedish care system is weak and is not supported by the management structure, IT system and models for resource allocation (Stierstedt, 2016). Consequently, the care services provided by single caregivers need to be integrated into a coherent process designed based on the older patient’s needs. Two types of integration were identified to align care services provided in different settings: organisational integration where services are managed within a single organisational structure and vertical integration where focus on ensuring smooth transitions between caregivers. A process-oriented way of providing care to older people requires a number of support processes. Caregivers need to communicate with the patient to understand her/his needs and shape the care process according to these needs. Coordinators assigned to patient and joint care planning activities are examples of these support processes. Further, integrated information systems need be developed that ensure an effective information sharing along the patient process.

Second, the previous research focuses on the integration of care in community, primary and hospital settings (WHO, 2016). However, our empirical findings highlight that we need to focus on the integration of one more setting: the older patient’s home. In the service management literature, the customer is seen to play an active role in the service creation and delivery processes (Grönroos and Ravald, 2011). According to the school of thought, called Service Dominant Logic (SDL), the customers are perceived as 'co-creators of value' instead of passive consumers (Vargo et al., 2008). This implies that value is not created and delivered by the health care service provider but emerges during the patient’s process of value creation (Grönroos and Ravald, 2011). Consequently, the health care providers are not producers of the value, but facilitators of the value creation processes. This perspective on health care delivery is valuable since patient’s home becomes a natural setting for providing care services for older people. Hence, health care providers need to facilitate the patient’s value creation at home. This was also clearly indicated in the case studies and among the key strategies to integrated care it was identified development of home-based care services and technical aids to support home-based care.

Third, patients’ needs change over time and new care services and new ways for health care delivery need to be developed. Traditionally, health care focused on treating acute and episodic illness (Lillrank, 2018). Patients back then experienced health problems more only temporarily and the duration of care provisions were more limited in time and scope (RAND, 2012). Today, health care needs to increasingly care for patients with chronic conditions, where the goals include life-long wellbeing and preventing complications or deterioration rather than curing. In line with this change also the structure, processes and working methods in health care must be renewed and developed. Instead of treating episodic illness in hospitals an increasing emphasis must be put on developing care service for managing chronic disease in outpatient settings. Examples of new services developed by the case organisations are day care unit, mobile teams and safe discharge process.

Summarising, the most important theoretical implications of the paper for achieving integrated care for older people are that fragmented care services need to be provided in a process-oriented way, extended to patient’s home and offered by new forms in outpatient settings. The paper provides several practical examples on strategies that have been implemented to provide person-centred and coordinated care delivered at the right time and in the right place.

Exploring Modularity in Healthcare Service Delivery

Gyan Prakash (gyanprakasha@yahoo.com)  
ABV-Indian Institute of Information Technology & Management Gwalior, India

Abstract

This paper explores and assesses modular healthcare service delivery. It follows a survey-based approach and the unit of analysis is specialized hospitals. A model linking constructs of professional competence, technological versatility, clear division of tasks, channelized flow of information, professional autonomy, and modular healthcare service delivery is proposed. Data were collected from 227 doctors and nurses dealing with out-patients services of tertiary care specialized hospitals. Findings will help practitioners in carving out customer involvement during the process, managing heterogeneity of customer request, decomposition of service offerings, standardization of interfaces with design and planning rules, mixing and matching of components.

Keywords: Healthcare, Modularity, Service delivery

Introduction

Healthcare service delivery involves network of participants such as specialised doctors, nurses, support service providers, insurance providers, governments, hospital administrators and end-users. They work in tandem to match the heterogeneous demand and aims to reduce the fragmentation in healthcare service delivery processes. Towards this modularization is expected to enhance flexibility (Bask et al., 2010) through reducing complexity in fragmented systems. Baldwin and Clark (1997) define modularity as configuring complex products or processes from independently designed smaller sub-systems that function together as a whole. This helps in clear division of tasks among the service providers. Modularization enables the simplification of processes as there is a reduction of interdependencies among the interactions (Ethiraj and Levintahl, 2004). Many authors have underscored the role of modularization in healthcare (Meyer et al., 2007; de Blok et al., 2013; Vahatalo and Kallio, 2015; Silander et al., 2017); however, modularization is not explored much in the context of highly specialized healthcare. Healthcare modularity studies have been carried out in areas such as mental care (Chorpita et al., 2005; Soffers et al., 2014), elderly care (de Blok et al., 2010, 2013, 2014) etc. Previous research has identified design aspects of service modularization such as customer involvement during the service process (Pekkarinen
and Ulkuniemi, 2008), managing heterogeneity of customer requests (Rahikka et al., 2011) and standardization of interfaces (Chorpita et al., 2005). This paper aims to explore and assess modular healthcare service delivery. Towards this the paper presents a model which relates the facilitators of modular healthcare service delivery. This model will help service providers to define and operationalise modularity in a more efficient manner.

**Literature review**

*Understanding modularity*

Demand for various types of healthcare services are increasing due to increased longevity of people. Healthcare service delivery is complex and place significant demands on providers to know more (knowledge), do more (work), manage more (activity), share more (information), and interact more (coordination among service providers) (IOM, 2001). Modularity involves dimensions such as components, modules, interfaces and packages. Components are parts that perform one clearly defined function in the final product or service offerings and represent a distinct portion of a product or service that function in an autonomous manner (Duray et al., 2000). They are the smallest units in which a product or service can be divided (Pekkarinen and Ulkuniemi, 2008). A module is conceptual grouping of one or more components that provide variants and substitutes that deliver similar functionality (Pekkarinen and Ulkuniemi, 2008). Interfaces are linkages which are shared among components. Interfaces manage interactions and connections between components when they are combined to deliver the service package (Salvador et al., 2002; Voss and Hsuan, 2009). Interfaces enable the mixing and matching of components and achieving a functional service package (Fixson, 2005). In healthcare, components can be grouped into modules such as care services, welfare services, safety services and housing services. Similarly, protocols, procedures, information aids, planning rules and standard lines of communication might all function as interfaces between components.

*The challenge of modular healthcare*

Healthcare involves heterogeneity that consists of distinct service fields which react to managerial methods in different ways (Lillrank et al., 2015). Patients need vary and require customised as well as standard services. Moreover, healthcare services are often categorized under different medical specialty departments (Porter and Lee, 2013). Division of tasks deter setting of common goals and at times different units operate in an independent manner. Traditionally complexity and high variety of patient needs have been managed within the patient-physician relationship. Consequently, tightly coupled service architecture has evolved within fragmented healthcare units which are characterized by strong professionalism, autonomy, and hierarchical levels. Where individual specialist’s discretion and experience play an important role in the decision making. Although some services are mass-produced, professionalism and autonomy are still strongly associated with the delivery of specialized hospital services, which leads to a conflicting co-existence of mass and professional services (McLaughlin and Kaluzny, 2000). This is further compounded by information asymmetry between professionals and patients (Lanseng and Andreassen, 2007). This asymmetry constrains the co-creation of services because patients may not be able to distinguish between their medical wants and needs (Berry and Bendapudi, 2007). Lack of patient involvement may act as inhibitor of healthcare modularity (de Blok et al., 2010). Evidence is discordant regarding the benefits of modularization in healthcare as studies show that modularization can be used both to increase customization in care (de Blok et al., 2013)
as well as to restrain it (Vahatalo and Kallio, 2015). Standardization is a prerequisite of effective modularization but can also challenge it by restraining customization, competition, and new service and technological innovations (Vahatalo and Kallio, 2015). Nonetheless, modularization and the modular service architecture can be used as a means to reduce costs, streamline information flow and enhance care coordination (Soffers et al., 2014).

**Conceptual model and research hypotheses**

*Linkage between professional competence and division of tasks*

In an organizational setting, professional competency describes excellence in performance. Professional competence involves number of competencies which are used to perform various occupational roles. Professional competence is a means by which organizations communicate which behaviours are required, valued, recognized and rewarded with respect to specific occupational roles (Fernandez et al., 2012). Professional competence ensures that service providers have a common understanding of the organization’s values and expected performance behaviours (Forsten-Astikainen and Heilmann, 2018). Such understanding will be better developed if the competencies are channelized through clear division of roles and responsibilities (Forsten-Astikainen et al., 2017). Clear division of tasks between professionals and the standardization of service components enable increased replaceability among professionals. Formally stated:

\[ H_1: \text{Professional competence positively influences clear division of tasks.} \]

*Linkage between technological versatility and division of tasks*

Technological versatility reflects the extent to which healthcare processes are facilitated through technological solutions. Adequate technological infrastructure helps in elimination of constraints, streamlining of processes (van Hoof et al., 2014) and management of heterogenous demand. Versatile use of technology enables channelized flow and effective distribution of tasks and responsibilities. Coordinated care supported by technological infrastructure enables the care providers in managing the heterogeneous demands of patients (Vahatalo and Kallio, 2014). Formally stated:

\[ H_2: \text{Technological versatility positively influences clear division of tasks.} \]

*Linkage between clear division of tasks and channelized flow of information*

Various professionals work together to deliver healthcare services. Clear division of tasks enable faster and timely scheduling of care delivery processes (Ericksson et al., 2017). Clear division of tasks result in improved level of information dissemination. This results in elimination of non-value adding activities and reduction in waiting times (Griffith, 2009; de Blok et al., 2014). In the out-patient care unit context, specified roles and responsibilities among service providers result in enhanced level of service delivery (Lavender et al., 2017). Formally stated:

\[ H_3: \text{Clear division of tasks positively influences channelized flow of information.} \]

*Linkage between clear division of tasks and professional autonomy*

In an organizational context, division of tasks set the course in which organizational and unit level decisions take place (Hickson et al., 1971). Professional competence of service providers determines their influence on organizational decision making (Connor, 1992). In healthcare service context, professional autonomy reflects delegation of power to make decisions while delivering care processes without being constrained by organizational procedures, financial concerns, performance measurement systems and
managerial control (Salvatore et al., 2018). The way professional autonomy is exercised depends on the organisational settings (Kuhlmann et al., 2013). Formally stated: 

$H_4$: Clear division of tasks positively influences professional autonomy.

**Linkage between channelized flow of information and modularity**

Modularity reflects the decomposition of complex processes into simple modules. Flow of information among these modules is critical (Soffers et al., 2014) and a channelized flow of information strengthen the underlying modular architecture. Formally stated: 

$H_5$: Channelized flow of information positively influences modularity.

**Linkage between professional autonomy and modularity**

Professional autonomy together with re-organization of services into independent units help in improving modular architecture (Silander et al., 2017). At care-unit level providers configure service delivery processes and design treatment protocols (de Blok et al., 2009; Rahikka et al., 2011). Professional autonomy enables conceptualization of modular design and results in enhanced level of quality care (Vahatalo and Kallio, 2014). Formally stated: 

$H_6$: Professional autonomy positively influences modularity.

**Methodology**

The paper follows a survey-based approach and the unit of analysis is specialized hospitals. Based on the review of literature a model linking constructs of professional competence, technological versatility, clear division of tasks, channelized flow of information, professional autonomy and modular healthcare service delivery is proposed. Data were collected from 227 doctors and nurses dealing with out-patients services through a survey of tertiary care specialized hospitals listed under the list of Joint Commission International-USA operating in India during January 2017 to June 2018. Partial least squares structural equation modeling (PLS-SEM) was used for data analysis. Empirical findings were analyzed in conjunction with the literature.

**Findings and discussion**

**Assessment of measurement model**

As suggested by Hair et al., (2017), first, the measurement model was assessed for validity and reliability of the indicators. Second, the structural model was evaluated to assess the strength of the hypothesized paths among the variables. The psychometric properties of scales were analysed through an assessment of discriminant validity and reliability. Table I depicts factor loadings. All factor loadings for indicators measuring the same construct are statistically significant (p<0.05), supporting convergent validity. As depicted in Table II composite reliabilities (CRs) and average variances extracted (AVEs) are above recommended minimums of 0.70 and 0.50, respectively. Thus, all factors demonstrate good internal consistency and high levels of convergence, supporting the reliability and validity of multiple-item scale. Similarly, square root of AVE of a construct comes out to be greater than its correlations with other constructs thereby, demonstrating discriminant validity. The Heterotrait Monotrait (HTMT) values for the indicators were calculated using the complete bootstrapping procedure of the SMARTPLS v3 software. All the values were below the acceptable range of 0.90 (ranging from 0.562 to 0.844) indicating the discriminant validity.

Cons.: Constructs, α: Cronbach’s α, * exogenous construct, **Square root of the AVE on the diagonal

Before analysing the structural model, the variance inflation factor (VIF) was assessed to compute multicollinearity. The VIF results for each construct, which were below threshold value of 5.0 indicate that collinearity issues between the constructs were absent.
Assessment of structural relationships

A $Q^2$ value of larger than zero implies that the exogenous constructs have predictive relevance for the endogenous constructs included in the model (Hair et al., 2017). The hypothesized relationships were tested using the PLS algorithm to generate the standardized path coefficients. As a follow-up analysis, a bootstrapping method was used to generate the significance of path coefficients. These results are summarized in Table III. As depicted in Table IV the standardized root mean square residual, normed-fit-index, and rms_theta were within the acceptable range. The chi-square values for the model were 436.374 and 474.719 for the saturated and estimated models, respectively.

The coefficient-of-determination ($R^2$) measures the predictive accuracy of the constructs. These values represent the amount of variability in the endogenous constructs of clear division of tasks, channelized flow of information, functional autonomy and modularity, which were 42.1%, 56.1%, 48% and 58.6%, respectively; and were explained by the respective constructs. These values are moderate and reflect predictive relevance and are shown in Figure 1.

![Figure 1 - Path coefficients in the structural model](image-url)
In the context of modular healthcare services, the posited relationship between professional expertise and clear division of labour comes out to be positive (path coefficient is 0.693). The respondents felt that their level of expertise in delivering quality care facilitates them to specify responsibilities. Clear division of tasks increases the effectiveness of internal interactions, thereby, facilitating the external service delivery processes.

Results show that technological versatility positively influences clear division of tasks (path co-efficient is 0.649). Technological versatility can act as a catalyst for conceptualization of modular services because technological approaches increase the efficiency of healthcare service delivery. The complexities of the care process can be simplified, leading to better resource utilization. Technology incorporated with clear division of tasks has the potential to transform healthcare service delivery through enhanced level of coordination and timely delivery of care processes.

Clear division of tasks positively influence channelized flow of information (path co-efficient is 0.422). Clear division of tasks serve the purpose of communicating expectations and managing treatment protocols. Assignment of service providers through clear division of tasks steer service providers towards a common goal. This in turn enable hospitals to achieve their strategic goals such as flexibility and adaptability. Goal alignment strengthens leadership and creates a channelized pathway for information sharing. Channelized flow of information helps in fostering relationships that help in managing uncertainties (Okhyusen and Bechy, 2009; Lillrank, 2012).

The relationship between clear division of tasks and functional autonomy comes out to be positive (path co-efficient is 0.391). When a hospital fosters a culture of proactiveness, autonomy, competitive aggressiveness, motivation, effective leadership, and build support infrastructure, then it could deliver enhanced level of care and achieve competitive advantage.

The posited relationship between channelized flow of information and modularity comes out to be positive (path co-efficient is 0.765). Respondents feel that channelized flow of information enable modular architecture. In modular architecture the service components are broken into modules which enhance overall efficiency of the system. These modules need to be connected for facilitating service delivery processes and connection between these modules need to be strengthened by channelized flow of information.

Finally, functional autonomy positively influences modularity (path co-efficient is 0.510). Each module has its own actors who will be performing service delivery processes. The functioning of a module can be enhanced when each actor acts autonomously under certain clinical guidelines. Functional autonomy helps the stakeholders to make better decisions about the care delivery processes.

Conclusion
This paper contributes to nascent literature on modularization of healthcare services. Conceptualization of model for modularization of healthcare services is the central contribution. Findings would be of interest to healthcare practitioners interested in modularization strategy. Findings of this paper will help practitioners in carving out
customer involvement during the process, managing heterogeneity of customer request, decomposition of service offerings, standardization of interfaces with design and planning rules, mixing and matching of components

Queuing model applicable in surgery OPD of a hospital to reduce the queue length of patients

Dr. Deoraj Prajapati  
Professor, Department of Mechanical Engineering,  
Punjab Engineering College (Deemed to be university), Chandigarh-160012 (India)  
E-mail: prajapatimed@gmail.com

Abstract:  
This case study has been done in Surgery Out-Patients Department (OPD) of one of the largest hospital of northern India in order to eradicate problem of overcrowding using data of eight Mondays. Using Queuing model, the utilization factor is also calculated for the surgery OPD on Mondays’ for various time intervals. The maximum arrival rate (λ=3.2235) of patients is observed during the time period of 8:00 AM – 8:30 AM, while it is minimum during the time period of 10:30 AM – 11:00 AM. This paper also presents cost analysis and adequate numbers of service counters to run the system efficiently.

Keywords: Queuing Model, Service Quality in healthcare, Medicine OPD, Waiting time, Customers satisfaction.

Introduction  
Queuing theory is the main aspect of waiting time models where discussion involves stochastic process. The main purpose of application of the queuing theory is to briefly investigate those queuing problems in the field of industries, transportation and business which are concerned times due to man and machine involve and the production of an item is done two or more distinct successive phases. Healthcare sectors are major sector of any nation those represent the depth of seriousness of country towards providing quality service to keep its people safe from any possible outbreak of diseases.
First of the queueing theory was developed by Erlang (1903) to eradicate the congestion problem of telephone traffic. Due to enormous number of calls, telephone operators were not able to handle this congestion and this need of proper management of queue problems kindled the need of queueing theory. Kim et al. (1999) analysed the processes of admission and discharge of patients from intensive care unit (ICU) in a public hospital of Hong Kong. It was found earlier that the decision-making scenarios of ICU were completely subjective and this behaviour initiated the need of this study to give specific criteria on which decisions could be made. De-Bruin et al. (2007) investigated the bottlenecks of emergency department in the specific area of cardiac in-patient flow. The main motto of the study is to find out the optimum number of beds required to minimize the adverse effect of refused admissions. Li et al. (2009) suggested a model which is based on combination queueing theory and goal programming, to make a multi-objective decision making system for Zichuan hospital, China. Queueing theory was used to estimate the arrival of patients and model M/PH/m was used with arrival pattern to be Poisson in nature. Kumar and Sharma (2012) studied the problems related to reneging decision of customers. They designed a new model to counter this issue and customers were convinced to stay in a line by different mechanisms. A simple queueing model was implemented on the queue problem with arrival and service times to follow negative-exponential distribution. Ameh et al. (2013) conducted a survey to reduce the waiting time and enhance the satisfaction level of patients. Among these 210 patients, 164 patients were found to spend two or less hours in queue and less than one hour with a doctor. They found that 144 patients were satisfied with their overall experience in a hospital. Gupta and Hira (2014) stated that the analyses of queueing systems depend on the use of random variables that are functions of time. Typically, these variables are used to describe discrete properties, such the number of jobs in system. Mustafa and Nisa (2015) studied the different departments of hospital to find a best suit to follow single or multi server queuing theory. Both M/M/1 and M/M/2 were implemented on queues to find remaining queue parameters. The general queue simulation was run on these parameters to analyse the network of queueing theory.

Xie et al. (2016) studied the concept of reverse triage policy where less wounded is given priority in giving a medical treatment. In this study, a queueing model was developed with transfers and abandonments by considering deterioration of condition of patients with the passage of time. They suggested to adopt dynamic control policy best suited according to a specific condition of a country and a hospital. Bahadori et al. (2017) studied the magnetic resonance imaging (MRI) department of hospital in Iran. The study emphasized on optimizing the performance of MRI department by using simulation and queueing theory techniques to increase the productivity of the department and satisfaction level of patients.

Botani and Hassan (2017) studied the pattern of queueing network of CT scan unit in Erbil teaching hospital in a quest to solve problems related to restriction of line and mitigate the issue of long waiting time. This study was conducted to find the suitable queueing model for the unit and run it on optimal level of performance. Bittencourt et al. (2018) applied queueing theory to manage the capacity of hospital and deal with the congestion problem due to increased demand of healthcare facilities. Queueing model was constructed on six months data of in-patients unit of university hospital. Main parameters that were under study were waiting time, bed capacity, probability of waiting, length of stay and others. Implementation of queueing theory helped to find a bottleneck in management of bed capacity of hospital. Maintaining admission and type of patients could easily help hospital management to increase their capacity.
Multi-channel Queuing theory (M/M/c): (FCFS/∞/∞)
The above model is a system with Poisson input and Poisson output with number of channels = c, where c is > 1, the capacity of line is infinite and first come first served discipline. Here the length of waiting line depends on the number of channels engaged. In case the number of customers in the system is less than the number of channels i.e. n < c, then there will be no problem of waiting and the rate of servicing will be μ n as only n channels are busy, each servicing at the rate m. In case n = c, all the channels will be working and when n ≥ c, then ‘nc’ elements will be in the waiting line and the rate of service will be μp n. Hira and Gupta (2014) suggested following equations to illustrate situations as follows:

\[ \sum_{n=0}^{\infty} p_n = 1 \]  
Eqn. (1)

\[ \sum_{n=0}^{c-1} p_n + \sum_{n=c}^{\infty} p_n = 1 \]  
Eqn. (2)

\[ \sum_{n=0}^{c-1} \frac{1}{n!} \left(\frac{\lambda}{\mu}\right)^n \cdot p_0 + \sum_{n=c}^{\infty} \frac{1}{n-c} \left(\frac{1}{\mu}\right)^n \cdot p_0 = 1 \]  
Eqn. (3)

Solving Eqn. (1.6), we will get the value of probability of zero customer in the system, \( p_0 \) expressed as

\[ p_0 = \frac{1}{\sum_{n=0}^{c-1} \frac{1}{n!} \left(\frac{\lambda}{\mu}\right)^n + \sum_{n=c}^{\infty} \frac{1}{n-c} \cdot \frac{c\mu}{c\mu-\lambda} \cdot \frac{c\mu}{c\mu-\lambda}} \]  
Eqn. (4)

Where:
\( p_0 \) = Probability of zero customer in the system, \( \mu \) = Service Rate, \( \lambda \) = Arrival rate, \( n \) = number of customers in the system, \( c \) = number of counters.

Various parameters of the multi-channel system can be calculated with the help of Eqn. (4)

Expected number of customer in the system, \( L_s \)

\[ L_s = \frac{\lambda\mu\left(\frac{\lambda}{\mu}\right)^c}{(c-1)!(c\mu-\lambda)^2} \cdot p_0 + \frac{\lambda}{\mu} \]  
Eqn. (5)

Expected number of customers in the queue, \( L_q \)

\[ L_q = \frac{\lambda\mu\left(\frac{\lambda}{\mu}\right)^c}{(c-1)!(c\mu-\lambda)^2} \cdot p_0 \]  
Eqn. (6)

Average time a customer spends in the system, \( W_s \)

\[ W_s = \frac{L_s}{\lambda} = \frac{\mu\left(\frac{\lambda}{\mu}\right)^c}{(c-1)!(c\mu-\lambda)^2} \cdot p_0 + \frac{1}{\mu} \]  
Eqn. (7)

Average waiting time of a customer in the queue, \( W_q \)

\[ W_q = \frac{L_q}{\lambda} = \frac{\mu\left(\frac{\lambda}{\mu}\right)^c}{(c-1)!(c\mu-\lambda)^2} \cdot p_0 \]  
Eqn. (8)

Probability that a customer has to wait, \( p \)

\[ p(n \geq c) = \frac{\mu\left(\frac{\lambda}{\mu}\right)^c}{(c-1)!(c\mu-\lambda)^2} \cdot p_0 \]  
Eqn. (9)

Probability that a customer enters the service without waiting, \( 1-p \)
\[ 1 - p(n \geq c) = 1 - \frac{\mu(\lambda)^c}{(c-1)!(c\mu-\lambda)^2} \cdot p_0 \]  \hspace{1cm} \text{Eqn. (10)}

Average number of idle servers,

\[ = c - (\text{average number of customers served}) \]  \hspace{1cm} \text{Eqn. (11)}

Utilization factor (rate): \[ \rho = \frac{\lambda}{c\mu} \]  \hspace{1cm} \text{Eqn. (12)}

**Introduction of the Hospital**

It is a premier medical and research institution in the northern India. It has educational, medical research, and training facilities for its students. This medical institute has bed capacity of more than two thousands. This hospital was declared centre of excellence in 1960 to endeavour to develop patterns of teaching in postgraduate medical education in various specializations as and producing specialists in several disciplines of medicine.

Surgery OPD is a second major OPD of PGIMER hospital and it takes 6% of load of all the OPD departments by itself only. The OPDs remains open from 8.00 AM to 11.00 AM for registration of patients. In order to access the total number of patients visited the Medicine OPD, data of two week are collected and summarized in the Table 2 which shows the average number of patients in week” days. It is observed that on average 518 numbers of patients visit in the Surgery OPD. This study focuses on Mondays’ data of the Surgery OPD and analysis is presented in this presented.

**Analysis of study**

First the study of the arrival pattern of patients arriving in OPD is done for specific time interval. The study of the number of patients arriving in a specific time interval of half an hour is done for the time period of five hours i.e. 6.00 AM to 11.00 AM. After analysing the data, the suggestions to increase/decrease the number of service counters have been given in this paper.

**Number of arrivals and Arrival rate (\( \lambda \))**

Total of four Mondays’ data of patients of Surgery OPD have been collected and average nos. of arrivals and average Arrival rate (\( \lambda \)) for each half an hour duration is shown in Table 2.

</table>
Table 3 show the possible number of counters those should be remained open to serve patients in all possible manners for all the working days. Utilization factor shows the effectiveness of the system. Its highest value of the effective system is unity and any value less than 0.7 is named as ‘Not Cost-effective system’ and if it is above unity; the system is considered to be inefficient. There are total of 3 nos. of counters to serve the patients in Surgery OPD and remain open throughout the three hours (8.00AM –11.00 AM) span period. The tentative numbers of counters; having utilization factor between 1.00 and 0.70 are taken to reduce the waiting time of the patients in Surgery OPD.

Following facts are observed from the Table 4:

- When the utilization factor is above unity, other parameters of queuing have not been calculated.
- The utilization factor reduces on increasing the numbers of service counters for all the time periods.
- The numbers of service counters are computed at various levels of utilization factors for all the time periods.
- Maximum arrival rate ($\lambda =3.224$) of patients is observed during the time period of 8:00 AM – 8:30 AM, while it is observed minimum during the time period of 10:30 AM – 11:00 AM.
- It is also observed that probability of zero patients in the system ($P_o$) is maximum (52.9%) during the time period of 10:30 AM to 11:00 AM and minimum (3.28%) during the time period of 10:00 AM to 10:30 AM.
- Average No. of patients in the system ($L_s$) is maximum (29.51) for the time period of 10:00 AM to 10:30 AM and minimum (0.89) for the time period of 10:30 AM to 11:00 AM.
- Average waiting time in the system ($W_s$) is maximum (14.75 min.) during the time period of 10:00 AM to 10:30 AM and minimum (1.09 min.) during the time period of 8:00 AM to 8:30 AM.

**Proposed System**

The working hours are divided into two halves intervals and recommendations are made accordingly. Table 4 shows the number of counters required for efficient working of the system at specific utilization factors.

Extra Manpower and cost analysis

Extra manpower is calculated for all the Mondays’ of the month by considering four hours as a working span of a single employee at the two values of utilization factors of 0.99 and 0.70. Cost analysis is done on Surgery OPD for Mondays’ by considering fixed and variable costs as shown in Table 5.

Table 5 shows the extra employees needed to be hired for efficient working and to reduce the waiting time in the system at the utilization factors of 0.99 and similarly yearly expenses for utilization factor of 0.70 is computed as 4,31,200 INR but not shown in the paper due to limitation of pages.

Conclusions

Surgery OPD is a major OPD of this hospital as it serves 518 patients every day. Total three numbers of counters are available in this OPD to serve various patients. It is found that most of the half-an-hour intervals of Surgery OPD is having utilization factor more than one. To reduce waiting time and to serve the patients in a better way, more numbers of counters are needed to be opened at the various levels of utilization factor. The purpose of the management should be to provide to quality service to the patients. It is computed that one and two more numbers of serving counters are required at the values of utilization factors of 0.99 and 0.70 respectively. Thus, the total expenditure for one year will approximately be 1,83,600 INR at the utilization factor of 0.99 while it is 4,31,200 INR at the utilization factor of 0.70.

Most of the studies have a common limitation of assuming an ideal model of process and sometimes the given assumptions of the model may be violated. This case study shows that how a simple implementation of basic models of queuing theory can be useful to handle majority of problems related to overcrowding of available resources in a proper manner in health care sector.
The present queening model in healthcare industry provides the necessary information to the management regarding system capability. There is strong need of top management commitment before implementing any queuing project. The top management should incorporate the quality initiatives in their business strategy in order to improve the healthcare quality.

References

Appendix A - Calculations for Table 3

Various calculations for Table 3 at the time interval of 8:00 AM to 8:30 AM for 17 service counters

(i) Probability of Zero Patients in the System (P_0) as per the Equation 4.

\[ P_0 = \frac{1}{\sum_{n=0}^{c-1} \frac{\lambda^n}{n!} + \frac{\lambda^c}{c!} \cdot \frac{\mu}{\lambda - \mu}} \]

Where:

- \( P_0 \) = Probability of zero customer in the system
- \( \mu \) = service rate = 1.0344
\[ \lambda = \text{arrival rate} = 17.5702 \]
\[ n = \text{number of customers in the system} = 527 \]
\[ c = \text{number of counters} = 17 \]

\[ p_0 = \sum_{0}^{484} \frac{1}{\left( \frac{17.5702}{1.0344} \right)^{527} 527!} + \frac{1}{\left( \frac{17.5702}{1.0344} \right)^{17} 17!} \cdot \frac{17 \cdot 1.0344}{17 \cdot 1.0344 - 17.5702} = 0.0008 \]

(ii) **Average** number of patients in the system, \( L_s \), using Equation (5)

\[ L_s = \frac{\lambda \cdot \mu}{(c-1)! (c \mu - \lambda)^2} \cdot p_0 + \frac{\lambda}{\mu} \]
\[ L_s = \frac{17.5702 \cdot 1.0344 \left( \frac{17.5702}{1.0344} \right)^{17}}{(17 - 1)! (17 \cdot 1.0344 - 17.5702)^2 \cdot 0.0226 + \frac{17.5702}{1.0344}} = 1203.4384 \]

Where: \( \mu = \text{service rate} = 1.0344 \), \( \lambda = \text{arrival rate} = 17.5702 \), \( n = \text{number of customers in the system} = 527 \), \( c = \text{number of counters} = 17 \)
